13. Therapeutic Properties of Ossein.

E. MAURIN (*Bull. de l'Acad. de Méd.*, November 2nd, 1926, p. 190) defines ossein as all the organic substance obtained from bone after the prolonged action of dilute hydrochloric acid. Ossein consists of a connective tissue stroma containing other tissue elements, vessels, osteoblasts and their secretory products, and forms an integral part of connective tissue. It is a quaternary, isomeric body with the formula $C_{12}O_4H_{10}N_2$; physiologically it is an imperfect albuminoid, lacking tyrosin, phenylalanin, and trytophan, and does not give Millon's and d'Adanckowicz's reactions. It is unable to regenerate true proteins, such as muscle tissue, and therefore it cannot be substituted for meat in the diet. It has been shown that the addition of its congener, gelatin, to a mixed diet lessens nitrogenous destruction. Ossein contains about 4 per cent. of mineral matter, the phosphates and carbonates of the bone remaining after its proper treatment with hydrochloric acid; it is suggested as a regenerator of connective tissue. Maurin has used it with beneficial results in tuberculosis, and during the war found it of great value in healing fractures, especially those in which union was tardy. Unlike gelatin, it does not cause any satiety or repugnance, and Maurin has used it in daily doses of from 30 to 50 grams for three to five months without any ill effects; he finds that both dietetically and therapeutically it is preferable to gelatin.

14. Iodine as a Prophylactic in Influenza.

F. LOMBARDO (*Rif. Med.*, October 25th, 1926, p. 1011), recalling the experience of Veyrieres, where the workers in an iodine factory nearly all escaped influenza during the 1917–18 epidemic, has tried the effect of an iodine vaporous solution in certain schools as a preventive procedure. In one classroom iodine vapour from a watery solution of iodine and potassium iodide was diffused once or twice a day, and in another room no such vaporization was used; in the first room hardly any influenza occured, while there were several cases in the other room. The solution used contained one part of iodine with two parts of potassium iodide and 300 parts of distilled water. It was also used as an inhalation, adding 50 c.cm. to water, in a steam kettle.

Ophthalmology.

15. Lateral Intracapsular Extraction of Cataract.

ACCORDING to VAN LINT (*Bruxelles-Méd.*, December 5th, 1926, p. 173) intracapsular extraction of cataract is the ideal operation. The two principal methods employed, that of Smith by pressure and that of Barraquer by aspiration, have not become generalized owing to the failures met with by other operators. Van Lint's procedure is as follows: During the evening before the operation three drops of eupthalmine (5 per cent.) are instilled into the eye and one drop of the same mydriatic one and a half hours, one hour, and half an hour before the operation itself. When the patient is in the operating-room palpebral akinesia is produced by injecting a novocain-adrenaline solution, and a retrobulbar injection of 2 c.cm. of novocain (2 per cent.) is also given. The eyelids, cheek, and forehead are cleansed with iodized alcohol, and anaesthesia is produced by the use of cocaine (2 per cent.) and adrenaline. When operating on the left eye the operator stands on the left side of the patient; for the right eye he stands behind the patient. After dissection of the conjunctiva, followed by incision of the external portion of the corneal border, peripheral iridectomy is performed, and two sutures, left untied, are inserted at the supero- and infero-external edges of the conjunctiva. Any blood in the anterior chamber is washed out with physiological serum. A cupping glass is placed over the crystalline lens; to this glass, after proper manipulations, the cataract will adhere when it is removed. The two sutures are tied with perfect coaptation, and oil and pilocarpine are instilled. After forty-eight hours the other eye is freed, and on the fifth day the diseased eye is examined and the dressings are replaced for two days more; the sutures are then removed and the patient allowed to wear smoked glasses. The majority of operators have abandoned the retrobulbar injection because of its paralysing effect on the extrinsic muscles, but van Lint maintains that in lateral excision this immobility of the eyeball, far from being an inconvenience, provides greater security for operative precision. Owing to [illegible] ase, and the excellent results obtained, that the intracapsular method of catar[illegible] entirely supplant the extracapsular one.

16. Production of a New Lacrymal Punctum.

B. GRAVES (*Amer. Journ. Ophthalmol.*, September, 1926, p. 675) describes an operation for dealing with cases of epiphora due to slight failure of contact of the lower punctum to the globe. After preliminary installation of 5 per cent. cocaine drops, some solid cocaine is placed on the conjunctiva of the inner end of the lower lid. After the punctum has been identified and a few drops of cocaine and adrenaline introduced into the canaliculus, a fine grooved probe (Critchett's) is inserted along the lacrymal duct. The groove of the probe is now turned towards the globe or even towards the bottom of the fornix. The canaliculus is now divided for not more than 2 millimetres along its course from the punctum, the cut being directed towards the lower fornix. The lower lip of the slit so formed is fixed with an iris forceps, slightly pulled upon, and cut off; this will leave a triangular opening with its apex downwards, and the opening will be in contact with the globe.

17. Post-influenzal Unilateral Neuro-Retinitis.

G. A. SCHALY (*Nederl. Tijdschr. v. Geneesk.*, October 23rd, 1926, p. 1853), who records an illustrative case, remarks that the occurrence of optic neuritis after influenza in not very uncommon as it is met with, according to Groenouw, in about 5 per cent. of all cases. The remarkable feature in Schaly's case, which was that of a woman aged 37, was the presence of a unilateral neuro-retinitis, with a fully developed star figure in the macula lutea without the presence of nephritis. The urine had been constantly examined and was always free from albumin, while the patient had shown no signs of nephritis. The star figure of non-nephritic origin has been fully described by Leber in his account of cases of pseudo-nephritic diseases of the retina.

Obstetrics and Gynaecology.

18. Partial Symphysiotomy.

E. ZARATE (*Gynécol. et Obstet.*, 1926, xlv, 5, p. 289), describing his method of partial symphysiotomy in dystocia from pelvic contraction, states that enlargement of the transverse dimension of the pelvis by as much as 5 cm. can be gained without risk of injuring the soft parts, so that delivery is easily accomplished with obstetrical conjugates of 8 cm.; smaller conjugates require Caesarean section. After division of the symphyseal fibro-cartilage and the superior part of the arcuate ligament, the bistoury is withdrawn and by hyperabduction of the thighs the separation of the pubic bones is increased. With the patient on her back and under general or local anaesthesia the hips and knees are flexed and the legs held in abduction by two assistants. The position of the upper border of the symphysis is marked on the skin, and the bladder is catheterized; the index and middle finger of the left hand are placed in the vagina, so as to thrust the foetal head upwards and the urethra to one side. The point of a knife of 4½ cm. blade is introduced 5 mm. below the superior border of the symphysis and penetrates the fibro-cartilage, which is divided from above downwards and obliquely until the arcuate ligament is reached and in part divided, when the separation of the pubes to the extent of one fingerbreadth is perceptible; the knife is now withdrawn and the wound compressed. By still further abduction of the thighs the separation of the pubes is increased to two or even three fingerbreadths, and pituitary extract is injected. After delivery the pelvis is not bandaged, but the knees are tied together; the patient gets up on the twelfth to the fourteenth day. The superior safety of Zarate's procedure as compared, for example, with Frank's technique is stated to lie in (1) the completely intra-ligamentary employment of the bistoury; (2) the conservation at the time of the section of the superior symphyseal ligament and a large portion of the anterior ligament, so that too brusque separation of the pelvic halves is prevented; and (3) the cessation of the symphysiotomy before there has been a risk of damaging the clitoris, its dorsal vein, the corpora cavernosa, or the urethra.

19. Treatment of Febrile Abortions.

E. KOTTLORS (*Zentralbl. f. Gynäk.*, October 9th, 1926, p. 2616) remarks that serological and bacteriological investigations have not led to any reliable means of assessing the virulence of infection, and thus estimating the gravity of prognosis in cases of abortion with pyrexia. Some observers have agreed with Winter in regarding curetting as contraindicated during the pyrexial stage if haemolytic streptococci are present; but of late haemolysis has been admitted by Winter himself, among others, to be not only an unreliable indication of virulence, but also a variable property even in the same strains of streptococci. The Ruge-Philipp test, in which the

utero-vaginal flora are regarded as virulent or non-virulent according as they do or do not multiply in the patient's defibrinated blood, has proved disappointing; the virulence of the organism, thus assessed, varies in the course of a particular case in accordance with the clinical progress or regress. The results, both of active treatment, in which curetting is performed in spite of pyrexia, and of expectant treatment, appear very similar when large series of cases are compared with respect to mortality and morbidity, but the stay in hospital is diminished by an average of two or three days after active therapy. It is generally admitted that active treatment (curetting) is useless if the infective process has passed the bounds of the uterus—as, for example, if parametritis or adnexal inflammation is present; but the clinical detection of extrauterine infection, especially in the early stages, is uncertain. Estimating the sedimentation time of the red blood corpuscles may be helpful, but is affected, apart from infective processes, by pregnancy and by severe anaemia. Kottlors prefers clinical to laboratory methods in deciding whether in a given case the uterus should be explored and emptied; he is guided by bimanual examination, the general condition of the patient, the appearance of the tongue, and the temperature. In curetting old-standing abortion cases where the os has become almost closed he prefers dilatation by a tent to the use of Hegar's instruments. Prophylactic injections of argochrome or similar preparations before operation are believed to diminish mortality and morbidity—less, probably, by any specific action than by increasing the physical powers of resistance.

20. Preconjugal Syphilis and Pregnancy.

A. VACCARI (*Ann. di Ostet. e Ginecol.*, October 31st, 1926, p. 660) records four cases which show that foetal survival and well-being are not always assured if a preconjugal syphilitic infection of the father has been treated with apparent adequacy. The infections had occurred respectively 3, 5, 5, and 10 years before marriage, and had been followed by adequate three years' treatment, the Wassermann test becoming negative. In each case, after one or more early abortions and/or premature deliveries of macerated foetuses, the Wassermann reaction was found to be negative in both parents. In two instances antisyphilitic treatment of the mother was now undertaken from the beginning of a later pregnancy, with satisfactory results. Vaccari suggests (1) that males in whom an antecedent syphilis seems to have been efficiently treated should receive a further course of treatment before marriage; (2) that at each pregnancy antisyphilitic medication in the wife should be instituted.

Pathology.

21. Cholesteraemia and Hyperpiesia.

E. THOMAS (*Arch. Mal. du Cœur des Vaisseaux et du Sang*, October, 1926, p. 641), discussing the cause of "essential" arterial hypertension, mentions that several French authors have found in renal and arterial affections an increased cholesteraemia, and deposits of this lipoid in the diseased arterial walls. When cholesterin is added to rabbits' food, arterial changes occur, but it is uncertain whether hypertension precedes or follows the arterio-sclerosis. Thomas has tried, by experiments on rabbits, to discover whether cholesterin itself has a hypertensive action and whether repeated intravenous injections of cholesterin can cause hyperpiesia. No ill effects followed the injection of 0.015 gram of cholesterin dissolved in 0.5 c.cm. of sunflower oil. The author noted the carotid blood pressure and then withdrew 5 c.cm. of blood for the estimation of the cholesterin content. The first dose of cholesterin solution was then given, and the blood pressure again estimated; the effect of the injection was either absent or very slight. The injections were repeated at intervals of three days, and after four to six weeks the blood pressure was measured, a specimen of blood taken, and an autopsy performed. Thomas found that though cholesterin had no immediate hypertensive effect, yet its repeated injection produced prolonged hypertension. In two rabbits the blood cholesterin content fell from the beginning to the end of the experiment. As cholesterin is eliminated very slowly by the kidney, and consequently accumulates in other organs, the author thinks that there is some ground for the hypothesis that this phenomenon is peculiar to certain individuals. There was no evidence that the accumulation of cholesterin in the suprarenal cortex produced excess of adrenaline in the blood, nor that an excess of cholesterin in the blood had any effect on endocrine glands, such as the hypophysis, which have a hypertensive action.

22. Serology of B. melitensis and B. abortus.

G. FAVILLI (*Lo Sperimentale*, October 25th, 1926, p. 396) has examined twenty-two strains of *B. abortus*, seven of *B. melitensis*, and five of *B. paramelitensis*, confining his attention to the effect of various methods of inducing non-specific agglutination. The three methods employed were agglutination by heat, by peptone, and by lactic acid. Thermo-agglutination is tested by heating a suspension of the organism in 0.75 per cent. salt solution to 90° C.; when the reaction is positive the bacilli form flocculi, which deposit in the usual way. In peptone agglutination a suspension of the organism in distilled water is added to 1 c.cm. of a 1 per cent. peptone solution. The three tests gave generally similar results; the thermo-agglutination and the peptone agglutination tests were absolutely parallel, but the lactic acid test had a wider range, affecting certain strains which did not respond to the other two tests. With one or two exceptions, the *abortus* and *melitensis* strains did not react to the thermo-agglutination or the peptone agglutination tests; the *paramelitensis* strains did so. The lactic acid test has been used to distinguish between *B. melitensis* and *B. abortus*, but the author found it quite valueless for this purpose. By subculturing a strain of *B. melitensis* every day for five days in 10 c.cm. of broth containing three drops of immune anti-*melitensis* serum the author observed the appearance of thermo and peptone agglutination. After twelve or thirteen passages the organism no longer reacted to specific agglutination with its own serum; it adopted a different mode of growth in the serum broth, giving a diffuse turbidity, and had thus assumed the properties of *B. paramelitensis*. Favilli suggests that *B. paramelitensis* may arise under natural conditions by the continued existence of *B. melitensis* in the body of an immune animal. From being a type reacting to specific but not to non-specific agglutination, it changes spontaneously to a type not reacting to a specific *melitensis* serum, but reacting to non-specific agglutination.

23. The Influence of Glucose on the Bactericidal Power of the Blood.

FOR testing the bactericidal power of the blood F. MASSARA (*Il Morgagni*, October 3rd, 1926, p. 1249) used the method of Wright, slightly modified to suit his own requirements. Blood was taken from the vein of a normal person, defibrinated in a vessel with glass beads, and distributed into three tubes, 5 c.cm. being placed in each. The suspension of bacilli was prepared by rubbing up one loopful of a twenty-four-hour agar culture either in physiological saline or in a 4.7 per cent. solution of glucose. To each tube of blood one drop of bacillary suspension was added, the mixture shaken thoroughly, and incubated for six, twelve, or thirty-six hours at 37°C. A drop of the mixture was then placed on an agar plate and spread evenly over the surface with a glass rod, or dropped into a tube of melted agar, which was then poured into a Petri dish. After incubation for one and two days the number of developing colonies was counted. Two organisms were used—*B. typhosus* and *B. paratyphosus* B; the results obtained with each were closely similar. Briefly it was found that the number of surviving organisms was greater when the suspension was in saline solution than when the glucose suspension was employed. The differences were not great, but frequently amounted to 20 or 30 per cent.; in one or two instances a difference of about 50 per cent. was noticed. The most-marked effect was observed after incubation of the blood organism mixture for twelve hours; if incubation was allowed to proceed longer the organisms multiplied so as to obscure the results. The author concludes that small quantities of glucose are able to increase the bactericidal power of the blood *in vitro* towards the particular bacilli employed.

24. Serological Classification of the Gonococci.

J. M. MIRAVENT, R. QUIROGA, and P. NEGRONI (*C. R. Soc. de Biologie*, November 12th, 1926, p. 1166) have attempted to classify the gonococci serologically. About fifty strains were collected from various sources and cultured for three months on ascitic agar. Four serums were prepared by the injection of rabbits with suspensions of the organisms. For purposes of agglutination the organisms were washed off a twenty-four-hour ascitic agar culture with saline solution, the fluid was centrifuged in order to remove autolysed forms, the sediment was again suspended in saline solution, and standardized. An equal volume of serum and suspension was used, and the mixtures were incubated at 55° C. for two hours. As a rule, [illegible] proved sufficient to classify the strains [illegible] ception of agglutinins test was, however, [illegible] the grouping reached by the direct [illegible] ; place forty-five strains in four definite serological groups; two strains agglutinated equally well with *two of the serums*. The number of strains in Group A was 16, in Group B 8, in Group C 9, and in Group D 12.

EPITOME OF CURRENT MEDICAL LITERATURE.

Medicine.

25. Pulmonary Embolism.

R. C. CABOT (*Boston Med. and Surg. Journ.*, December 2nd, 1926, p. 1068) reports a case of pulmonary embolism in a man, aged 27, who complained of weakness, vertigo, and haemophysis after working for two days exposed to fumes from a composition rubber. At 15 years of age he had painful and swollen joints, especially the knees, and a slight attack of chorea, since when he had been well—serving for two years in the army and doing hard work. The attack appeared to be cardiac in nature and due to mitral stenosis resulting from the chorea; pulmonary infarction caused haemoptysis, and a friction rub developed later in the left axilla with slight dullness and some coarse inspiratory râles at the left base. Cabot considers the whole attack from the time he became dizzy and weak while at work as being pneumonic, originating possibly in an infarct thrown off from one of the heart valves as the result of an added subacute endocarditis. The man recovered sufficiently to perform light clerical work, but two years later he had an attack of nausea and vomiting with marked cyanosis and irregular cardiac action and some return of haemophysis. After a satisfactory recovery of compensation he attended as an out-patient, but later became orthopnoeic and very cyanotic, with paroxysms of tachycardia which ended fatally. The autopsy revealed a large adherent infarct in the left lower lobe, the pulmonary artery leading to it being thrombosed; the heart was dilated, and there was marked mitral stenosis. Cabot regards the original attack as being due to an acute pulmonary infarct occurring in an apparently healthy man and not as the result of any industrial poisoning from fumes from the rubber. He suggests that the clinical picture of such an occurrence is a sudden onset, prolonged pyrexia simulating pneumonia, and subsequent recovery.

26. The Prognosis of Angina Pectoris and of Coronary Thrombosis.

P. D. WHITE (*Journ. Amer. Med. Assoc.*, November 6th, 1926, p. 1525) recommends the separate classification of angina pectoris and primary coronary thrombosis. With regard to the prognosis in angina pectoris, hypertension, coronary thrombosis, syphilis, arterio-sclerosis, weak heart-sounds, abnormal T wave in electro-cardiogram, and especially cardiac enlargement, are more often found in patients with angina pectoris who die in a few years than in those who survive. Usually severe pain indicates a grave prognosis, as does the presence of one or more of these unfavourable factors. The prognosis is fairly good if the heart, blood pressure, and electro-cardiogram are all normal; in such cases early death is possible but unlikely. Probably, in the majority of cases, death is due to acute or chronic coronary occlusion. In a series of 200 cases the average duration of life after the onset of angina pectoris was 4.2 years, with 134 of the patients still living. Sex, occupation, and the direction of radiation of pain did not affect prognosis in this series. The average age at onset made a slight difference, the age of patients still alive after five years being 56, while that of those dying in less than five years was 60. White thinks that there are four factors which help to determine a good prognosis, with occasional exceptions. A patient with a sensitive nervous system who develops angina pectoris under unusual stress is a good risk provided that he shows little or no evidence of heart disease. The pain is caused by severe or moderate exertion and not induced by slight exertion, and adequate treatment causes a good response. The author adds that many patients with definite angina could pass a rigid life insurance examination by concealing their histories. These patients have true angina, but usually do well when treated properly. Any patient suffering from angina pectoris should avoid hurry, worry, over-exertion, over-eating, and severe weather. Rest, either on a voyage to warmer climates, or even when imposed by accident or surgical operation, has prolonged many lives. Cervical sympathectomy for angina pectoris is still on trial. With regard to the prognosis in coronary thrombosis many patients survive an attack for some years in good or fair health. The average duration of life after an attack in a group of 62 patients, half of whom are still alive, is nearly two years. Sex and age at the first attack appear to make little difference to the prognosis. Hypertension, arterio-sclerosis, and syphilis scarcely modify it. The heart was enlarged in the majority of patients, both living or dead. Weak heart sounds and congestive heart failure make the prognosis graver. The presence of fever or paroxysmal auricular fibrillation with an attack of coronary thrombosis made no difference in prognosis in the series; pericarditis was rather more frequent among patients who died. The electro-cardiogram did not help, but the very slow pulse of complete heart-block was a bad sign. Intraventricular block was more common among survivors. Attacks of angina pectoris prior to an attack of coronary thrombosis appear to worsen the prognosis. Prolonged rest and regular habits gave satisfactory results in the majority of these 62 patients.

27. The Myoclonic Form of Tuberculous Meningitis.

P. RIBIERRE and P. RENAULT (*Paris Méd.*, November 27th, 1926, p. 430) state that numerous cases have been recorded illustrating the difficulty in distinguishing between the acute stage of epidemic encephalitis and the various forms of meningoencephalitis, especially those due to syphilis or tuberculosis. The clinical symptoms are sometimes misleading, and the examination of the cerebro-spinal fluid does not always decide the nature of the case. Spinal lymphocytosis may be found in some cases of encephalitis and be absent in tuberculous meningitis. Excess of sugar in the spinal fluid is inconstant in encephalitis and has only a relative diagnostic value, while a normal quantity of glucose in the cerebro-spinal fluid may be found in tuberculous meningitis. It is rare for myoclonus to become so pronounced a symptom in tuberculous meningitis as to suggest the diagnosis of epidemic encephalitis. A case of this kind was recently observed by the authors in a man aged 50 who had been operated on a few weeks previously for renal tuberculosis. Examination of the cells, albumin, and sugar in the cerebro-spinal fluid showed nothing characteristic, but after two hours' centrifugalization two or three characteristic tubercle bacilli were found. The diagnosis of a terminal tuberculous meningitis was thus established although a necropsy could not be obtained.

28. Acute Articular Rheumatism Treated with Antistreptococcal Serum.

T. BARUFFALDI (*Rif. Med.*, October 25th, 1926, p. 1012) gives his experience in the treatment of 200 cases of acute articular rheumatism with antistreptococcal serum; he claims complete success in all cases. As tested by the von Pirquet reaction the number of cases which gave a positive result was rather striking, especially in the more chronic types. He gave a full dose of the serum (at least 30 c.cm.) as early as possible; no bad effects on any cardiac complications present were noted. When albuminuria or acute Bright's disease was present, these conditions were favourably influenced by the serum. In about half the cases a scarlatiniform eruption, lasting two to four days, appeared about the second week after injection. Where an early local reaction or non-febrile urticaria developed, the scarlatinal rash seldom appeared. Marked improvement in the joint troubles followed immediately after the exanthem. The treatment is said to be not contraindicated in chronic apyretic rheumatic affections, but in them not much benefit is seen. During the serum treatment the usual antipyretic and antirheumatic drugs should not be given. In only one case was any anaphylactic symptom observed.

Surgery.

29. Treatment of Haemorrhoids.

W. E. M. MITCHELL (*Canadian Med. Assoc. Journ.*, November, 1926, p. 1358), in discussing the treatment of haemorrhoids, emphasizes the necessity for a correct diagnosis and a clear conception of the underlying pathology. In those cases in which no definite cause can be discovered the treatment is considered under the headings of palliative, by injection, and operative. Palliative treatment consists in regulating the bowels with liquid paraffin after an initial soap enema, and manual reposition of any piles which do not recede spontaneously. The anus and surrounding skin must then be cleansed with soap and water and completely dried; this is followed by the free application of calamine lotion on boric lint kept *in situ* by a T-bandage. After a week of such treatment an opinion can be formed as to whether resort to injection will suffice or whether operative measures will be needed. Cases suitable for injection are those in which the piles are neither thrombosed nor inflamed, and the base of attachment is not wider than their greatest diameter, and in

which there is no general prolapse of the pile-bearing area. Such types of haemorrhoids can be efficiently and painlessly treated by injection without interference with the patient's ordinary mode of life. The permanence of cure by this method is still uncertain, but in suitable cases there has been no recurrence after two years. Other types of haemorrhoids require operation by ligature and excision. Mitchell considers forcible dilatation of the sphincters unnecessary. The pedicle is isolated by dividing with scissors the modified skin of the anal canal at the level of the lowest point reached by the base of the pile, which is separated from its lower attachments by cutting deep to its base, thus isolating a definite small neck containing the vessels of the pile.

30. Non-malignant Stricture of the Oesophagus.

A. HEINDL, jun. (*Deut. Zeit. f. Chir.*, November, 1926, p. 252) records his observations on 137 cases of non-carcinomatous stricture of the oesophagus admitted to the First Surgical Clinic of Vienna University between 1901 and 1925. Of the total cases 116 were due to corrosives: of these 47 were in children under 16 years of age, 48 were in women, and 21 in men; 36 of the cases were due to swallowing lye. The predominance of the female sex is explained by their choice of corrosives for suicidal attempts. The remaining 21 were caused by disease of the oesophageal wall due to diphtheria, peptic ulcer, oesophagitis, extra-oesophageal causes such as *tuberculosis, and congenital malformations. The prognosis* is absolutely bad in the last set of cases, but in the others it depends on the severity of the original disease. The method of choice in dealing with corrosive strictures is the passage of the bougies in mild cases, if necessary with the aid of the oesophagoscope, and in severe cases gastrostomy as well, especially when the stenosis becomes more pronounced in spite of the passage of bougies. Little benefit was derived from injections of fibrolysin and thiosinamin. Of the 116 stenoses due to corrosives 21 were treated by bougies, with one death due to perforation, 4 received no treatment, and 91 underwent the following operations: gastrostomy in 85 cases, gastro-enterostomy in one case, and jejunostomy in five cases. The subsequent history of the 91 cases was as follows: 14 died, 17 were treated by bougies, 35 underwent retrograde catheterization, 7 had a plastic operation performed, and the remainder received no further treatment.

31. Solitary Cyst in Horseshoe Kidney.

H. VIETHEN (*Zentralbl. f. Chir.*, October 16th, 1926, p. 2655) records a case in a man, aged 32, who apart from gastro-intestinal catarrh during the war had always been healthy. It was not until after the war that he began to complain of abdominal pain, especially in the right hypochondrium. The pain only lasted for a short time, and was sometimes colicky and sometimes burning. There had never been any jaundice, but there had often been vomiting of bile during the attacks. On examination there was distinct tenderness in the epigastric region, where an indefinite tumour corresponding to the position of the gall bladder could be felt. A diagnosis of cholecystitis was made and conservative treatment was at first employed, but as the pain grew much worse laparotomy was performed. A cyst the size of a child's head was found arising from the right side of the horseshoe kidney. Complete recovery followed the removal of the cyst. The absence of any symptoms pointing to renal disease, apart from an attack of haematuria several years previously, was a remarkable feature of the case.

Therapeutics.

32. Saline Injections in Gastric and Duodenal Ulcers.

T. BÁRSONY and G. SZEMZÖ (*Med. Klin.*, November 5th, 1926, p. 1721) have employed intravenous injections of 10 per cent. saline solution in 25 cases in which there had been previously operations for gastric or duodenal ulcer. Every second or third day an injection was given of 10 c.cm. of this solution, and the treatment was repeated ten to fifteen times. The patients were allowed to go about, but were kept on a meatless diet so as not to interfere with the test for occult blood. No alkali or other treatment was given unless the injections alone were insufficient. Some of the patients treated had not responded to dietetic and medicinal treatment. In fourteen of the cases all symptoms disappeared after several injections, in three they were relieved, in three others relieved only when combined with other means, and in five there was no improvement. Freedom from symptoms lasted varying times, but after eighteen months recurred in every patient who had reported. A lasting cure was therefore not effected, but the method gave freedom from disabilities for some little time. The authors consider it worth trial, either alone or combined with other means, and they find that no other ambulatory treatment is more successful. The saline treatment has many advantages over protein therapy. It causes no rise of temperature or marked focal reaction; it lessens the nausea and retching, and does not affect the quantity or acidity of the gastric secretion. In some cases occult blood persisted even in the absence of symptoms, and this is attributed to bleeding from newly formed, delicate granulation tissue.

33. The Iodine Treatment of Exophthalmic Goitre.

D. MASELLI (*Il Policlinico*, Sez. Med., November 1st, 1926, p. 565), after a full consideration of the recent work in the treatment of Graves's disease by iodine, and personal observation of 14 cases, sums up the rather contradictory results of various authors as follows. In nearly every case the exophthalmos remains unchanged. The thyroid gland becomes somewhat smaller and harder, and there is less bleeding at the operation. Metabolism and the gastro-intestinal and nervous symptoms are benefited, the body weight increases, the tachycardia lessens, and the blood condition improves. Contraindications of the iodine treatment are the presence of symptoms of tracheal compression (as in these cases suffocation may occur), grave symptoms of circulatory insufficiency, and pulmonary tuberculosis. It is essential that the patient shou d be kept in bed. Iodine treatment in the early cases renders the patient a much better subject for operative measures; the *condition termed* by Americans toxic adenoma is unsuitable for the administration of iodine. Patients who show no improvement in the metabolic index should not continue the treatment. Although it seems quite common for some early improvement to take place, these remissions are seldom of long continuance, and in a few cases iodine makes the patient worse at the very outset.

34. Sodium Salicylate in Epidemic Encephalitis.

D. DÉNÉCHAU, J. PÉIGNAUX, and H. FRUCHAUD (*Bull. et Mém. Soc. Méd. des Hôp. de Paris*, November 25th, 1926, p. 1587) observe that although the value of intravenous injections of sodium salicylate in treating epidemic encephalitis is well known, their experience in the case of a child aged 2½ is worth recording on account of the severity and multiplicity of the symptoms, which necessitated intensive treatment. Intravenous injections were rendered particularly difficult by the child's youth, so that the jugular veins, the cephalic, and the basilic veins had to be utilized in succession. When first seen, after having had coryza for three or four days, the child had a rectal temperature of 102° and was vomiting; there was a strong odour of acetone in the breath, and acetone was present in the urine. As the child had had an attack of acetonaemic vomiting a year previously the usual treatment was employed, and was followed next day by the disappearance of all traces of acetone. The rectal temperature, however, oscillated between 102° and 104°, but there were no localizing symptoms and no meningitic reaction or torpor. On the following day the spinal fluid was found to contain a great excess of glucose and a slight excess of albumin; encephalitis was suspected. On the third day the temperature rose to 105.5°; the patient was drowsy and there was paresis of the right upper limb; 1 c.cm. of fresh turpentine was injected into the outer surface of the left thigh. The temperature continued to rise and the child grew worse rapidly; he became deeply comatose with general muscular relaxation, and six days after the onset the pulse was so weak and rapid that he appeared to be dying. Next day there was a slight improvement, although the temperature remained at 104°. The fixation abscess developed normally. The child recovered consciousness and cried and coughed frequently. The paresis of the right arm disappeared, choreiform movements became general, and the features became characteristically mask-like. On the ninth day the temperature fell to 100°, and a few injections of uroformine were given as well as intravenous injections of 5 per cent. sodium salicylate solution in a 4.7 per cent. isotonic glucose serum. The veins were so small that one was exposed freely at the flexure of the elbow, and 1 gram of sodium salicylate was injected easily; a violent reaction followed, with partial collapse. In spite of this the salicylate injections were continued, both intravenously and intramuscularly, in doses of 1 to 1.7 gram thrice in twenty-four hours. The choreiform movements were intense and continuous, and the child could scarcely swallow a few drops of milk. On the twentieth day he began to improve steadily, and ultimately made a complete and permanent recovery. D. DÉNÉCHAU (ibid., p. 1592) records five cases (with four recoveries) of acute infection resembling meningitis, corresponding to neuraxitis. He thinks that the type of epidemic encephalitis is changing and that it no longer attacks only the mesencephalic nuclei, and attributes the four recoveries to intravenous injections of sodium salicylate. The fatal case was that of a man aged 36, who

improved slightly at first, but his temperature rose and he died in coma. In every case the Wassermann test was negative. The author believes that, in addition to typical lethargic encephalitis, there are not only neurotropic infections resembling myelitis, radiculitis, or polyneuritis, but also meningeal reactions, curable, in spite of their severity, by intravenous injections of sodium salicylate.

35. Digitalis in Paroxysmal Auricular Tachycardia.

S. A. LEVINE and H. BLOTNER (*Amer. Journ. Med. Sci.*, November, 1926, p. 660) report four cases of the successful treatment of paroxysmal tachycardia by digitalis in large doses. In two of these the regular administration of [illegible] prevent recurrence, but thorough [illegible] proved effective in rendering the [illegible] attacks, though in each instance when digitalis was stopped the attacks at first recurred. The authors emphasize the importance of giving digitalis in full and continued doses; in one of their cases in which it had been given in small amounts for several months it seemed to be of no value until considerably increased. They believe that the use of insufficient doses explains why digitalis has been unfairly discredited in the treatment of paroxysmal auricular tachycardia. The continued oral administration of quinidine was found unsatisfactory, but in two patients the intravenous injection of 0.2 to 0.3 gram stopped the paroxysms at once. *The authors, however, believe that repeated administration of digitalis in doses of about half a gram three times a day, followed later when digitalization is complete by doses of 0.1 gram, can be of great value when the attacks of tachycardia are frequent and incapacitating.*

Neurology and Psychology.

36. Narcolepsy in a Child.

A. A. WEECH (*Amer. Journ. Dis. Child.*, November, 1926, p. 672) reports a case of narcolepsy occurring in a child aged 7, and comments on its rarity, since this disease generally occurs about the time of puberty or during adult life. Weech's patient, after severe epistaxis due to injury, developed attacks of drowsiness, *which increased in frequency and depth. Some* hallucinations were present, but there were no symptoms suggesting epilepsy. The electrical conductivity of the child's skin was much increased, and in this connexion the author refers to Richter's view that the estimation of this resistance furnishes an objective method of determining the depth of sleep. Some attacks of emotional asthenia occurred. The child quickly improved under treatment with thyroid extract in doses of 4 grains daily. The basal metabolic rate before treatment was 18 per cent. below normal, but returned to the normal as the child's condition improved. An account is also given of a case of symptomatic narcolepsy occurring in a boy, aged 12, who did not improve under treatment with thyroid extract. The author suggests that narcolepsy is not a primary disease, but should rather be considered as a symptom-complex due to injury of a localized brain area.

37. The Nature of Epilepsy.

L. B. ALFORD (*Med. Journ. and Record*, November 3rd, 1926, p. 551) contends that epilepsy is an extrapyramidal motor disturbance. These conditions are due to lesions of the corpus striatum, substantia nigra, *red nucleus, and possibly other* basal cell groups, the best known being chorea, tremor, and athetosis, but torsion spasm and myoclonus may be added. The pathological process is a selective degeneration due to innate weakness, termed "abiotrophy" (Gowers). Conditions dependent on this process are the progressive muscular atrophies and dystrophies, Friedreich's ataxia, Huntington's chorea, and oto-sclerosis. Epilepsy is included among the abiotrophies on account of the influence of heredity, post-natal onset, and progressive mental deterioration. The latter has been ascribed to the use of bromides, to exhaustion, and to mental conflict: all may contribute to accentuate it, but it is probably an expression of the same nervous constitution as that which gives rise to the convulsions. The author believes that although epileptic attacks are usually discontinuous and extrapyramidal disturbances are continuous, there is no reason to conclude that continuity is essential to the latter, which vary with emotion and voluntary effort, and cease during sleep. The idea of the infracortical origin of convulsions is not new, and it has long been believed that the clonic stage represents infracortical activity. In 1924 Sterling described extrapyramidal epilepsy and referred to spasmodic attacks in epidemic encephalitis. Krisch states that the generalized tonic attacks may be regarded as an excited state of the motor tegmental system in which cerebellar, striatal, and cortical regulation has broken down. Alford cites the case of a family in which the mother and a son were epileptic, while a daughter had typical moderately advanced Huntington's chorea. Myoclonus epilepsy is an abiotrophy, presenting marked mental deterioration, an epilepsy closely associated with extrapyramidal disturbance. If it is conceded that the specific factor in the causation of epilepsy is a degeneration in one of the extrapyramidal nuclei, exciting factors of the attack will be provided by influences that heighten nervous tension.

38. Headache as a Prodromal Symptom of Disseminated Sclerosis.

C. FOIX, MAURICE-LÉVY, and Mme SCHIFF-WERTHEIMER (*Rev. Neurol.*, November, 1926, p. 423) call attention to the importance of headache as one of the prodromal symptoms of disseminated sclerosis. In three married female patients, aged 26, 40, and 30 years respectively, intolerable headache was present, and the Wassermann reaction of the cerebro-spinal fluid was negative. One patient became blind in a few weeks; the headache was accompanied by frequent attacks of vomiting, but this was not typically cerebral. She had some evidence of descending optic neuritis. The gait, exaggerated tendon reflexes, right ankle clonus, right hemiparesis, and the presence of Babinski's sign in the right foot all suggested disseminated sclerosis. The patient later became able to recognize near objects, count fingers, and move about *a room without accident. The hesitant gait and hemiparesis* disappeared completely after a course of daily intravenous injections of half a gram of sodium salicylate in 10 per cent. glucose serum. The patient also received 4 grams of sodium salicylate by the mouth or rectum. The second patient had a staggering gait, due to inco-ordination, brisk tendon reflexes, Babinski's sign on both sides, and occasional vertigo. In spite of the negative Wassermann reactions, the patient received a course of antisyphilitic treatment, which produced no improvement and was discontinued after an attack of paraplegia had supervened. Four weeks later the patient began to improve and the headache disappeared. Three years later the condition was practically stationary. The third patient complained also of severe headache, unrelieved by analgesics, bromides, and antispasmodics. The headache was worse at night and radiated from the forehead to the suboccipital region. Although the Wassermann reaction of the cerebro-spinal fluid was negative, the colloidal benzoin reaction was strongly positive. Bismuth was administered, but it did not relieve the headache. Six months later the gait was staggering and the patient was unstable when standing with the eyes closed; co-ordination in the lower limbs was slightly uncertain. C. FOIX, J. A. CHAVANY, and MAURICE-LÉVY (ibid., p. 429) have employed intravenous injections of sodium salicylate for the relief of headache with favourable results, and report the case of a woman, aged 31, who had had a sudden attack of violent headache associated with repeated vomiting and inability to stand. The headache persisted for some months and the patient developed definite symptoms of disseminated sclerosis, which disappeared after intravenous injections of sodium salicylate. The patient appeared absolutely normal in every respect and returned to duty as a hospital nurse. In a young woman, aged 26, whose initial symptom was intense headache with total blindness following an optic neuritis which came on shortly after a very definite right hemiparesis, the latter disappeared rapidly, and the vision was restored sufficiently for her to count fingers correctly, after intravenous injections of sodium salicylate. Another woman, aged 38, who had had difficulty in walking for four years, had spastic paralysis and vertigo: she was relieved by three courses of intravenous injections.

Obstetrics and Gynaecology.

39. Gynaecological Sequels of Appendicectomy.

R. CONDAMIN (*Lyon Méd.*, December 5th, 1926, p. 643) believes that pelvic sequels of appendicectomy, particularly in the pouch of Douglas, are much more common than has been supposed. He describes the case of a girl who was quite healthy until appendicitis occurred at the age of 14. The surgeon recommended delay for a few weeks before performing an interval operation, but three weeks later a still more severe attack occurred. An immediate appendicectomy was performed, and turbid serum was seen in the pouch of Douglas. For five years subsequently the patient suffered from persistent nausea, anorexia, abdominal pain, especially on walking, alternating constipation and diarrhoea, and severe dysmenorrhoea, associated with uterine anteflexion and adhesions in the pouch of Douglas. Systematic massage of these adhesions, and dilatation of the cervical canal, produced a rapid and complete restoration to health. The author

believes that in a large number of cases exploration of Douglas's pouch would furnish an explanation of the partial or complete failure of the operation to relieve the patients' symptoms. Gibson has reported 550 appendicectomies with 102 failures to give amelioration, and 65 cases in which the results were satisfactory, although the dyspepsia persisted. Enriquez estimated the percentage of failures as nearly 30 per cent. Condamin affirms that rational treatment after appendicectomy will prevent those disappointing sequels, *but warns against massage of the pouch of Douglas after* an attack of appendicitis, when an operation has not been performed, since it might provoke a fresh attack.

40. Cervical Pregnancy.

P. SCHNEIDER (*Arch. f. Gynäk.*, December 2nd, 1926, p. 302) remarks that cervical pregnancy probably occurs more commonly than is generally supposed, dislocation following at an early stage without well marked clinical symptoms. He agrees with Mueller that critical examination casts doubt upon almost all of the twenty-three recorded cases of cervical pregnancy. In what he believes to be a case of true pregnancy in the cervix a nine weeks ovum, 3 cm. by 2 cm. in size and covered completely by chorionic villi, was removed from one lip of the cervix. Externally, erosion had almost penetrated through the vaginal aspect of the portio into the lateral fornix. Decidual reaction was noted microscopically both in the cervix and in the corpus uteri, the cavity of which above the internal os was 6 cm. in length. The patient sought treatment for severe bleeding without antecedent amenorrhoea, and the preoperative diagnosis was uterine abortion.

41. M. IOLKIN (*Zentralbl. f. Gynäk.*, November 27th, 1926, p. 3071) mentions 40 cases of placental attachment in the cervix uteri; no child was born alive and one in three of the mothers died from haemorrhage as well as one in ten from infection. The case is recorded of a patient, aged 35, who twice had had abortion induced on account of nephropathy during early pregnancy. The first months of the next pregnancy were characterized by frequent and painful micturition and blood-stained vaginal discharge. A copious haemorrhage occurred a week before labour, which was accompanied by abdominal pain and repeated rigors. The cervix was found to be replaced by a hemispherical tumour bulging into the vagina, and the external os was of rudimentary dimensions. A diagnosis of abortion with adhesions at the external os having been made, dilatation and exploration showed a cervical canal to be absent, but the cervix, to which the placenta was attached near the external os, apparently occupied by a gestation sac and a foetus 24 cm. long, which was delivered feet first. From the gestation sac access was secured with difficulty into a higher and smaller cavity, regarded as the corpus uteri, the lining of which showed decidual reaction.

42. Simultaneous Intrauterine and Extrauterine Pregnancy.

A. G. J. HERMANS (*Nederl. Tijdschr. v. Geneesk.*, November 6th, 1926, p. 2097), who records an illustrative case, states that the earliest examples of this condition were described by Duverney in 1708, and by Geoffrey in 1722. The rarity of its occurrence is shown by the fact that Weibel in 1905 found only one example among 140 cases of extrauterine pregnancy; 244 cases were collected by von Neugebauer in 1913, and 250 by Sippel in 1922. The situation of the extrauterine pregnancy may be in various parts of the right or left tube, without any predilection for either side. Sometimes an ovarian, tubo-ovarian, or interstitial pregnancy has been found. The age of the patients has ranged from 21 to 42. Most of the patients were multiparae, but Duverney's case was in a nullipara, and one occurred in a woman who had had nineteen children. As regards the maternal mortality, Weibel states that 40 out of 111 died—from infection, septicaemia, haemorrhage, or embolism. Simultaneous intra- and extrauterine pregnancy may end in various ways: (1) Sooner or later the extrauterine pregnancy ruptures and causes the death of the mother, and at the necropsy an intrauterine pregnancy is also unexpectedly found. (2) Shortly before the mother's death expulsion of the intrauterine ovum takes place. (3) After operative removal of the ruptured extrauterine pregnancy the intrauterine pregnancy goes to full term. The case recorded by Hermans occurred in a woman aged 40, the mother of five healthy children, the youngest of whom was 7 years of age. *Symptoms of ruptured extra*uterine gestation developed in the third month of pregnancy, and at the operation, in addition to a ruptured left haematosalpinx, an intrauterine pregnancy of about three months was discovered. The following day, about twelve hours after the operation, miscarriage occurred and a foetus 7 cm. long was born. The mother made a good recovery.

Pathology.

43. The Serological Relations of Acid-fast Bacteria.

J. FURTH (*Journ. of Immunol.*, October, 1926, p. 273), who has made a serological study of the tubercle and acid-fast bacilli, has come to much the same conclusions as those reached during the past two or three years by English workers. This is of all the more interest because the method used chiefly in this country has been agglutination and absorption of agglutinins, whereas the author has used the complement-fixation test, often combined with absorption. The results show that acid-fast bacilli are divisible into four main groups—the mammalian, avian, cold-blooded, and saprophytic acid-fast. With the exception of a single bovine strain, all the organisms of human and bovine origin tested fell into one homogeneous group. In the avian group three subtypes were found; in one of these subtypes Arloing's agglutinable strain and Kedrowsky's non-chromogenic leprosy strains were classified together. The number of strains of the cold-blooded and saprophytic acid-fast types examined was insufficient to result in any definite conclusions on their classification; the strains of the former group showed little *similarity to each other or to other members of the acid-fast* group, whereas the strains of the latter group appeared to conform to one main type. In conclusion the author considers that his observations disprove the old hypothesis that all acid-fast bacilli contain one common antigen, present in varying proportions in different strains; they show rather that the differences between the members are qualitative.

44. The Nature of the Biliary Function.

J. P. SCHNEIDER (*Minnesota Med.*, November, 1926, p. 631) confirms Mueller's theory that unless bilirubin is allowed to flow into the bowel where bacteria can reduce it at least in part into urobilin, the urobilin will disappear from both bile and urine, and not reappear, irrespective of the degree of damage to the liver or of blood destruction. He also agrees with Rous that in normal circumstances the variations in the amount of haemoglobin circulating as blood from day to day find a direct expression in the amount of bilirubin discharged into the bile. Mann showed that the conversion of haemoglobin into bilirubin occurs in the territory of the reticulo-endothelial system as a whole, particularly in the marrow, spleen, lymph glands, and the Kupffer cell areas of the liver. The liver in this respect is an excretory and not primarily [illegible]n, which explains why, in the haemo[illegible]d contains so much bilirubin and not [illegible] is on its way to the liver, not to the kidney. Bilirubin for the liver, as well as the kidney, in man is a "threshold" substance, and its threshold is many times higher than that of urobilin. Schneider describes in detail his tests on liver and gall-bladder function, and believes that it will eventually be found that many bacterial toxic actions do not produce the signs of liver injury in consequence of liver-cell destruction but as a result of haemolytic action. That this blood destruction can be very rapid, and that recovery will occur when the bacterial invasion is transient, is evident from the cases of acute, [illegible] recently reported by Lederer, Brill, a

45. Sedimentation of the Red Cells.

A. FIGUERIDO and L. BILBAO (*Arch. de med., cir. y esp.*, October 9th, 1926, p. 56) record their observations on the sedimentation test, and come to the following conclusions. The so-called *reaction of Fahraeus, which* is not specific, is of value for the study of the course of tuberculosis, especially in patients who have undergone treatment by hygienic measures, sanocrysin, and artificial pneumothorax, since it is more sensitive than other clinical and laboratory methods, and should form part of the routine examination owing to the simplicity of its technique. In gynaecology the reaction is an indication of the intensity of the inflammatory process, whatever its nature may be. The existence of foci with large peripheral walls may pass unperceived by the reaction. Syphilis and anaemia accelerate the reaction. In extrauterine pregnancy with haemorrhage the reaction is not of the same value as in inflammation.

46. Production by Drugs of Reducing Substances in Urine.

R. D. LEAS (*Journ. Lab. and Clin. Med.*, October, 1926, p. 15) recalls that the administration of salicylates, uric acid, creatinine, chloroform, cinchophen, and tolysin cause reducing substances to appear in the urine, giving rise to confusion when the copper reduction test is the only one employed. These drugs, with the exception of tolysin, do not, however, reduce Benedict's solution *in vitro*. The reducing substances rotate the plane of polarized light to the left, and do not produce ozazones nor ferment yeast. They disappear from the urine in from twenty-four to eighty-six hours.

EPITOME OF CURRENT MEDICAL LITERATURE.

Medicine.

47. Muscular Cramp.

G. W. FITZ (*Boston Med. and Surg. Journ.*, October 28th, 1926, p. 854) describes a physiological cure for cramp, based upon a clinical study of about 100 cases. Accepting the alkalosis theory of the cramp state, he aims at rapidly reducing the relative alkalosis of the blood and tissues concerned in this tetanic state by holding the breath and rebreathing, so preventing the escape of carbon dioxide from the blood in the lungs. A rubber-cloth bag of three pints capacity with an opening large enough to cover the nose and mouth, and stiffened with soft copper wire shaped to the face, is pressed tightly to the face in rebreathing, accidental suffocation being impossible since failure of attention allows the bag to fall sufficiently to admit fresh air. At the first sign of cramp the breath is held and the empty bag applied, the breath being released into it as late and as slowly as possible. Since there will be too little air for rebreathing, a little air is sucked in at each inspiration when the bag empties, thus permitting the deepening respirations caused by the increasing venosity of the blood. The process acts so quickly that in some instances the cramp is aborted, while in others it is stopped merely by holding the breath and slow, shallow breathing; but success depends upon treating the first twinge, since a long inspiration or an attempt to speak may allow the cramp to develop sufficiently to require the use of the bag for rebreathing. Fitz considers that alkalosis appears to allow the lower motor nerve cells to act independently of their controls in continuing muscular contractions in opposition to inhibitory stimulation normally producing relaxation; susceptibility to cramp may indicate an overactive respiratory control favouring alkalosis by hyperpnoea, or instability of the neuro-muscular elements which are hypersensitive to slight transitory blood reaction changes. Carbon dioxide retention makes it easy to determine whether alkalosis is an associated factor in tetanic seizures of unknown origin.

48. Herpes Zoster following Injury.

H. T. SCHREUS (*Dermatol. Woch.*, October 30th, 1926, p. 1606) mentions three cases of herpes zoster following lumbar puncture, in two of which the eruption occurred in the region of the puncture, and in the third the vesicles were on the scalp. *This would seem to indicate, as the etiological factor,* some injury to the spinal cord through alteration in pressure, rather than a primary lesion of the ganglia. Similar cases following spinal anaesthesia have been recorded by several writers. It may be that the injury stimulated some latent herpetic infection of the ganglia, or that the eruption followed some injury in a region of lessened resistance. Schreus records the case of a boy, aged 11, who had been treated for Hodgkin's disease for three months by periodical irradiation of the spleen and the cervical and axillary lymph glands. A second series of irradiations was commenced eight months later, the treatment being given every second or third day on the right and left sides alternately. Six weeks later an extensive herpetic eruption appeared over the left side of the neck and the left shoulder and infraclavicular region. The eruption was accompanied by severe pain; some of the vesicles became gangrenous, and the lesions did not heal entirely for fourteen days. The etiology remained obscure.

49. Clinical Forms of Myocardial Infarction.

L. GALLAVARDIN and L. GRAVIER (*Ann. de Méd.*, September, 1926, p. 161), in a paper based on the study of twenty-nine cases, define three varieties of myocardial infarction: (1) forms with a sudden and dramatic onset, usually proving fatal in a few days; (2) those with a subacute and progressive course, lasting for some months and little benefited by treatment; and (3) infarctions with an insidious onset. The first variety, which is much rarer than might be supposed, is probably due to obliteration of a large branch of the coronary artery, giving rise immediately to extensive infarction, or less frequently to a smaller infarct occurring in an already damaged heart. The symptoms may be those of simple cardiac collapse without very marked dyspnoea, sometimes accompanied by Cheyne-Stokes breathing, restlessness at night, and insomnia. In other cases the symptoms are those of pulmonary oedema. The cardiac condition is always associated with a considerable degree of shock resembling that found in peritonitis. Two distinct types of the second variety occur. In the first, which may be described as cardioplegic, the symptoms are those of asystole chiefly affecting the left side of the heart, and consisting in marked breathlessness on the least exertion, nocturnal dyspnoea, and slight attacks of pulmonary oedema. The second type, which is less frequent, is characterized by the cachectic condition of the patients, the dyspnoea, though present, being of less importance. The third variety, of which there were only eight examples in the series of twenty-nine cases, may be subdivided into three groups according as (1) the infarction merely caused an aggravation of pre-existing cardiac insufficiency, as in subjects of Bright's disease or chronic myocarditis; (2) the infarction was accompanied by a syndrome of left ventricular insufficiency, in which digitalis was almost entirely ineffective; and (3) the infarction was entirely latent or larval.

50. Prophylaxis of Measles.

A. L. HOYNE and B. M. GASUL (*Journ. Amer. Med. Assoc.*, October 9th, 1926, p. 1184) remark that the one outstanding objection to the general adoption of convalescent measles serum for the prophylaxis of the disease is the difficulty in obtaining a suitable supply of this agent. The objection to the plan adopted by Rietschel and others of using the serum of adults with a past history of measles is that as much as 30 c.cm. of adult serum must be injected instead of the small doses of 2.5 to 5 c.cm. of ordinary convalescent serum. The present authors administered an immune goat serum, prepared according to Tunnicliff's method, to thirty-nine infants and children exposed to measles; thirty-four were protected and five had mild attacks without complications, whereas of nine infants who did not receive serum all but one contracted measles and two died. Serum rashes occurred in only 13 per cent. of the cases and lasted only one or two days. No untoward results from the serum developed.

51. Congenital Syphilis in Uniovular Twins.

F. WEISS (*Arch. f. Kinderheilk.*, August 7th, 1926, p. 18), who records an illustrative case, states that though congenital syphilis in twins is rare, a twin pregnancy, according to Gallo, is somewhat more frequent in syphilitic than in non-syphilitic women (3.9 per cent. as compared with 2.5 per cent.). Since 1918 only one other case, reported by Fischl and Steinert, has occurred at the German University Clinic at Prague. In Weiss's case the twins resembled each other in their appearance, nutrition, and behaviour as regards exogenous infection (nasal diphtheria). Both developed congenital syphilis at the age of 5 months, the first symptom in both cases being a blood-stained nasal discharge containing *Spirochaeta pallida*. The eruption was absent in one twin and ill marked in the other, who subsequently developed enlargement of the liver and spleen, which did not occur in the first. The onset of the disease was simultaneous in both cases, but the intensity of the symptoms differed in the two infants.

52. Diabetes in Denmark.

A. NORGAARD (*Ugeskrift for Laeger*, October 28th, 1926, p. 982) publishes statistics showing how great has been the increase in the morbidity and mortality from diabetes in Denmark during the past generation. In the decade 1890-99 the deaths from diabetes in Copenhagen and the other Danish towns numbered 402 for men and 271 for women; there was thus a considerable preponderance of male over female cases. In the five-year period 1920-24 the deaths from diabetes throughout Denmark among males and females numbered 1,110 and 1,157 respectively, the sex disparity having ceased to exist. Since 1923 the number of deaths has begun to decline, the deaths for the whole country and both sexes numbering 502 in 1922, 478 in 1923, and 424 in 1924. The author is not sure whether this decline is merely an oscillation depending on those obscure factors which determine the periodic fluctuations of certain diseases, or whether it is a reflection of the influence of insulin. In 1890 there were only 10 cases of diabetes treated in the large hospitals in Copenhagen; by 1911 this number had risen to 107, and by 1924 to 608. In a series of 76 cases in which accurate information was obtainable as to the duration of the disease from start to finish it was found that it was shortest in childhood and in advanced old age. In the insurance age—between 15 and 62—the average duration of the disease from the appearance of its first symptoms to the death of the patient was about five years. The disease ran, on the average, a shorter course in females than in males. The average number of deaths from diabetes in Denmark every year being 468 (the average for the last three years 1922-24), and the average duration of the disease being five years, the author calculates that

there must be between two and three thousand diabetics in Denmark. On the assumption that one-fifth to one-quarter of these patients undergo insulin treatment, it is calculated that the insulin patients number between five and six hundred. During the last eighty years in Denmark the consumption of sugar per head has increased about eight times.

53. Accidental Rashes in Varicella.

UGO DE GIRONCOLI (*Riv. di Clin. Ped.*, September, 1926, p. 623) reviews the literature, including the paper by J. D. Rolleston (JOURNAL, 1907, i, p. 1051), on accidental rashes in varicella, and records two illustrative cases. The transient erythema which may precede or accompany the eruption of varicella is regarded by some as so uncommon that in several textbooks it is not even mentioned. The rash, which is scarlatiniform in six-sevenths of the cases, and may therefore give rise to errors of diagnosis, is characterized by its sudden appearance and localization on the trunk and proximal ends of the limbs, by the fact that the subjacent skin is pale and not yellowish as in scarlet fever, by its rapid disappearance, though it may persist for five or six days, and by the absence of pruritus and subsequent desquamation. The eruption is generally regarded as a toxic erythema induced by paralysis of the capillaries in the cutaneous area which is already affected by various influences usually endogenous in origin. The author's two patients were brothers aged 7 months, the subjects of congenital syphilis, in whom a scarlatiniform eruption appeared on the second and third days of varicella respectively and faded without being followed by any desquamation or albuminuria.

54. The Dick Reaction.

E. KRAMÁR and D. FRANCZISZCI (*Monatsschr. f. Kinderheilk.*, September, 1926, p. 420), as the result of observations on 500 infants and children at the pediatric clinic at Pécs, report that the Dick reaction was positive in 48 per cent. of those who had had scarlet fever and 60 per cent. who had not had it. In confirmation of the observations of von Bókay and Johann it was found that positive Dick tests were most frequent between the third and fifth years. The authors state that in the majority of scarlet fever patients the reaction becomes negative during the disease, but the behaviour of the reaction, however, is not so regular as has been maintained, so that they do not regard the test as of any diagnostic value. Repeated Dick tests on a single individual did not always give similar results, the same person being sometimes found susceptible and sometimes immune. These spontaneous variations in the Dick reaction were found more frequently in debilitated children who had been exposed to different infections than in the healthy. In order to avoid unpleasant results from prophylactic inoculation intracutaneous injection was employed instead of the usual subcutaneous method. By this means it was possible to render the Dick reaction negative in 95.2 per cent. with decidedly smaller doses, so that the severity of the local reaction was considerably reduced and no general reactions were observed.

Surgery.

55. Surgical Treatment of Vesical Tumours.

E. S. JUDD (*Journ. Amer. Med. Assoc.*, November 13th, 1926, p. 1620) thinks that surgeons have been too ready to give up radical operations for malignant disease of the urinary bladder; vesical tumours are for a long time confined to this organ and adjacent tissues, and are therefore pre-eminently suited to surgical treatment. He considers that tumours of the bladder from the standpoint of treatment should be classified in three groups. The first group includes benign tumours, most of which are papillomas and may be treated by endoscopic methods. The diagnosis should be made with certainty, for if there is any question about the nature of the tumour, a radical operation is necessary. The second group should include all malignant cases in which the process is still confined to the bladder and all cases in which the diagnosis is questionable. The treatment indicated is radical removal of the growth and reconstruction of the bladder, if that is possible. He believes that there are certain instances in which the entire bladder should be removed if there should be a reasonable prospect of eradicating the malignancy thus. He has performed total cystectomy many times with excellent results. In most of these cases the operation was for exstrophy of the bladder, and while the operative procedure is entirely different in these cases from that in cases of carcinoma, nevertheless the operation was usually performed on children with poor physical development. The results in these cases show that the procedure is entirely practical, that subsequent function is about normal, and that often these patients have comfortable lives and are able to carry on any ordinary occupation. Although total cystectomy with transplantation of the ureters to the rectum is not an ideal procedure, it should, nevertheless, be performed more often for carcinoma of the bladder. Drainage of the renal pelvis to protect the anastomosis of the ureter to the bowel will reduce the risk in certain cases. With more experience and development of the technique, total cystectomy can be made a reasonably safe and satisfactory operation. Judd adds that too often he has tried to reconstruct the bladder after performing subtotal cystectomy, and the result was a long-continued sinus infection with fatal termination, although the carcinoma did not recur. Total removal in some of the more favourable cases should bring satisfactory results. In the third group should be placed those cases in which the malignant growth was too extensive for removal. If the lesion extends to the perivesical tissues, fixing the bladder firmly to the prostate and seminal vesicals or to other organs in the pelvis, it is not advisable to attempt to remove it. For growths too extensive for radical removal surgical diathermy offers the best prospect. This treatment should be employed in cases in which carcinoma of the bladder is less extensive, if there is some contraindication to the radical operation, such as cardiac or renal disease. Up to the present time the failures have been due to too conservative operative procedures, and often to delay in operating while some less radical plan is persisted in.

56. Malaria and Surgical Operations.

N. N. NASAROFF (*Deut. Zeit. f. Chir.*, November, 1926, p. 330) states that the prevalence of malaria in Russia in recent years has given the operating surgeon several problems to decide. During the last two and a half years Nasaroff has had the opportunity of studying at the surgical clinic of Saratov University 28 cases in which there was a history of malaria from six months to two years previously, and an operation caused a recurrence of the disease. As a general rule the process of healing and cicatrization was slower and the tendency to ulceration greater in these patients than in those who had never had a previous attack. Nasaroff's conclusions are as follows. The surgeon should inquire whether the patient who needs an operation has ever suffered from malaria; he should endeavour to prevent the operation causing a relapse and aggravating the general condition. Malarial patients should not be operated on until the fever had subsided. If the operation cannot be performed, prophylactic administration of quinine is indicated. Surgical affections in persons debilitated by malaria run a protracted course and not infrequently have a bad prognosis.

57. Adenomyoma of the Gall Bladder.

L. BIANCALANA (*Arch. Ital. di Chir.*, October, 1926, p. 539), who records an illustrative case, states that benign tumours of the biliary tract are rare, as is shown by the fact that in 1913 Bravet could only find thirty-eight cases on record. Their situation in order of frequency is the fundus of the gall bladder, the lower end of the common bile duct, the cystic duct, and the hepatic duct. Histologically the tumour may be a fibroma, myxoma, lipoma, myoma, papilloma, adenoma, cystoma, or a combination such as fibro-adenoma, adenomyoma, and so on. Cystic and a lenomatous growths of the gall bladder are the least uncommon and show considerable variations in size. Among 288 specimens from cholecystectomies performed in the course of seven years Abell found a benign tumour in eight, five being adenomata and three simple papillary adenomata. Aschoff and Bacmeister found an approximately equal number (3 per cent.) in the form of thickening of the fundus of the gall bladder and constituted partly by the normal epithelium of the biliary tract and partly by distinctly calciform cells. Four adenomyomas of the gall bladder were described by Louis Nicod at the Pathological Institute of Lausanne in 1921. These were also situated on the fundus of the gall bladder, and ranged in size from a pea to a hazel nut. In Biancalana's case of adenomyoma of the gall bladder, which occurred in a woman, aged 30, who died of septicaemia following abortion, the tumour, which was the size of half a hazel nut and situated in the fundus of the gall bladder, was found by accident at the necropsy, as there was no clinical history indicating its presence.

58. Mesenteric Cysts.

M. CORNIOLEY (*Lyon Chir.*, September–October, 1926, p. 565) records in detail two cases of cysts of the mesentery and discusses the pathology, symptoms, and treatment of this condition. It appears that these cysts may be present for a long period without causing definite symptoms beyond some slight disorders of digestion. Then they may suddenly give rise to urgent signs requiring immediate treatment. The acute onset may start with violent abdominal pain, vomiting, distension, complete constipation, and rapid pulse without

elevation of the temperature. In such cases and in the absence of a palpable tumour a diagnosis of volvulus may be made. An actual volvulus has in some cases been found present together with the cyst. A sign peculiar to this condition is a sense of abdominal ballottement noticed by the patient, while when acute symptoms supervene there is abdominal rigidity over the tumour. The mesenteric cyst is usually found to be movable, while cysts of retroperitoneal origin are generally fixed in position. Rectal and vaginal examination may be useful in diagnosing the condition from other tumours of pelvic origin. The most serious complication is suppuration of the contents, which is associated with rise in temperature; rupture of the cyst may sometimes occur. Treatment consists in removal of the tumour; as a rule there are few adhesions, and the operation may be quite simple. If, however, the intestine is adherent to the cyst it may be necessary to remove a coil of intestine at the same time and perform an end-to-end anastomosis. Occasionally in enucleating the tumour the blood supply to the gut may be damaged and resection again becomes necessary. The results after operation are good and recurrence of the cyst is almost unknown.

Therapeutics.

59. Opium as an Adjuvant to Insulin.

C.-G. DANIELSON (*C. R. Soc. de Biologie*, October 29th, 1926, p. 1058) states that for a long time it has been thought that preparations of opium diminish diabetic hyperglycaemia. Ahlgren recently found that morphine in the presence of glucose stimulates tissue oxidation in a manner similar to insulin, while Ross showed that morphine produced hyperglycaemia. Trendelenburg and other authors think that morphine acts as an irritant on the origin of the nerves of the suprarenal medullary zone, and accordingly provokes an increase of adrenaline secretion. Lewysohn and Klercker have found that a subcutaneous injection of 50 mg. of pantopon (*an opium preparation*) *into dogs leads to no appreciable* modification in the amount of blood sugar, large doses being required to increase the glycaemia. Cannon, McIver, and Bliss, experimenting on cats, and Abe on rabbits, have shown that injections of insulin cause an increase in adrenaline secretion. Since opium has been shown to have a favourable action in the treatment of diabetes it would be expected to give a reaction contrary to the hypoglycaemic one of insulin. *Danielson, in a series of experiments on rabbits, found that* a subcutaneous injection of 0.5 mg. of opium per kilo of body weight caused a hyperglycaemia, attaining its maximum (0.16 to 0.212 per cent.) one and a half hours after the injection, and returning to the normal after two hours. After an injection of 7.4 mg. the maximum (0.132 to 0.234 per cent.) was reached in one and a half hours, the return to normal taking four hours; if 50 mg. were injected the maximum of 0.105 to 0.245 *per cent. was reached in one hour, and the return to* normal in five and a half hours. The amount of insulin injected was always 0.35 Toronto units per kilo of body weight, and this caused a reduction in the blood sugar from 0.045 to 0.132 per cent., the return to normal taking from five to six hours. If insulin and opium were injected at the same time, a less-ening of the insulin hypoglycaemia was obtained only with the largest (50 mg.) dose of opium; with other doses the *hypoglycaemia increased. The author believes that* although opium and insulin stimulate the medullary substance of the suprarenal, causing a hypersecretion of adrenaline, a substance which causes hyperglycaemia, yet the two products increase the hypoglycaemia when administered together, and that opium possesses the power of augmenting the hypoglycaemic reaction of insulin.

60. Modern Treatment of Lupus.

HALKIN, P. FRANÇOIS, and L. DEKEYSER (*Ann. de Derm. et de Syph.*, October, 1926, p. 572) examined 275 patients under treatment for lupus at the Nottebohm Hospital at Antwerp, and conclude that cutaneous tuberculides indicate a generalized tuberculous infection, and demand general treatment. Artificial heliotherapy gave the best results, and clinical observations indicated the superiority of carbon arc lamps; *infra-red irradiation* was not found of use. Tuberculin treatment was only useful in attenuated tuberculosis. Local light treatment caused the least disfigurement in tuberculous lupus. Intensive regional treatment considerably reduced the length of treatment. The authors find carbon dioxide snow useful in many forms of cutaneous tuberculosis; it is indicated in lupus erythematosus. Other methods of local treatment, especially scarification and curetting, combined with pyrogallo-creosote ointments, are said to be useful in some cases; they may be combined with light treatment; *x*-ray treatment proved disappointing. General examination of the lymphatic glands and lungs is important; phototherapy *without this precaution may cause inflamed glands to* suppurate and induce pulmonary complications. The patient's weight and temperature must be watched. Benzyl-cinnamic ether is said to improve the general condition in tuberculous lupus and to hasten healing of the lesions; it has an elective action on pharyngeal and other mucous lesions. Some successes following gold treatment have been reported, but moderate doses may cause headache, fever, and diarrhoea. The older surgical methods of curetting or excision are useful in many cases. The use of high frequency currents has been recommended; this treatment may cure tuberculous skin lesions which have resisted other treatments. This treatment is most rapid and certain in lupus limited to the face, and the scars compare favourably with those resulting from other methods. In extensive lesions prolonged treatment is required. Radium treatment is useful in exuberant forms, and the cosmetic effects are satisfactory.

61. Medical Treatment of Chronic Peptic Ulcers.

D. H. ARNOTT (*Canadian Med. Assoc. Journ.*, October, 1926, p. 1238), believing that patients, even after operation for the cure of chronic gastric and duodenal ulcers, must be just as careful in their diet as before operation, has practised medical treatment for the cure of these conditions during the last twenty years. He follows one general plan of treatment, whether the disease be gastric or duodenal. For one year the patient is allowed only two meals in the day, separated by an interval of five to six hours; nothing but water is allowed between meals. The intention is to secure daily fourteen continuous hours of physiological rest for the stomach and duodenum. Should there be retention of food, the stomach is washed out with warm water four or five hours after the second meal. Fatigue is avoided and the patients are required to lie down for fifteen minutes immediately after meals. With these limitations patients may, as a rule, be allowed to follow their occupations. As regards the diet, fowl and fish are to be preferred to heavy meats, and milk soups are much better than stock soups. Arnott forbids tea, coffee, tobacco, spirits, wine, beer, highly spiced sauces or foods, nuts, bran, brown bread, salads, and raw fruit and cooked fruit containing seeds, such as raspberries; also any other articles of diet which the patient has found to be a source of trouble in digestion. These rules are to be followed for one year, at least. A mixture containing bismuth subnitrate, rhubarb, cascara, and magnesia is continued steadily for six months; the amount of cascara is regulated to ensure one natural action daily.

62. Iodine in Pulmonary Tuberculosis.

ACCORDING to L. DAVID (*Bruxelles Méd.*, November 1st, 1926, p. 31) any case of tuberculosis with limited lesions and of slow evolution is suitable for iodo-therapy. As intramuscular injections are given, injectable iodates must be administered, radio-active camphorated iodine being preferred by the *author. He injects daily for thirty days one ampoule con*taining 1 c.cm., and repeats the injections after intervals of fifteen days, during which all medication is stopped. David mentions thirty-eight cases in which this treatment was employed beneficially with the following results. General euphoria was produced with a constant diminution of asthenia, the fever abated, and the lesions improved, while the weight increased and tachycardia diminished. He *states that the eupnoeic and tonic cardiac action of camphor* must be remembered, but that this is trifling and temporary owing to the small amount present in the injections, and he insists that the treatment of pulmonary tuberculosis with radio-active iodine leads to an arrest of the morbid process and to the disappearance of signs of bacillary toxicity; this substance exerts both a direct antitoxic and also a general stimulo-defensive action.

63. Lumbar Puncture in the Treatment of Epilepsy.

G. P. U. PRIOR and A. T. EDWARDS (*Med. Journ. of Australia*, October 16th, 1926, p. 507) report 53 cases, and call attention to the value of lumbar puncture in the treatment of epilepsy and some allied convulsive disorders; the recovery rate in idiopathic epilepsy was 95 per cent. Benefit, often immediate and complete, followed the withdrawal of from 20 to 60 c.cm. of cerebro-spinal fluid in cases of status epilepticus, and it was found to be desirable to drain thoroughly until a sufficiently low pressure was obtained, as shown by the flow becoming synchronous with respiration. The authors always administered an initial soap-and-water enema, followed, if necessary, by an enema containing 2 drachms of potassium bromide, with 20 grains of chloral hydrate; in the less severe cases these, or even the soap enema alone, will cause a cessation of the attacks. The method was also found useful in convulsions due to arterio-sclerosis and general paralysis of the insane, and, by calming the patient, beneficial results

have been obtained in chronic mania. Improvement occurred in epileptics who were not actually having fits at the time, but who were very restless or even maniacal. Examination of the cerebro-spinal fluid of sixteen patients for acetone gave a positive result in nine; eight of these were in status epilepticus and one was a general paralytic suffering from severe convulsions. Acidosis is said to be common in status epilepticus, and the same metabolic disturbance may cause death without convulsions in epileptics. It is suggested that epilepsy may be the result of an interference with the detoxicating functions of the liver, whereby toxins of normal or abnormal alimentary functions are allowed to reach the systemic circulation.

64. Salol in Urinary Sepsis.

P. BAZY (*Bull. de l'Acad. de Méd.*, November 22nd, 1926, p. 225) recommends salol as a useful neutralizer of the toxins or to destroy the organisms which cause febrile attacks in patients after catheterism. He has found this drug invariably successful in his own cases, and has also used it in cases of acute infection of the urinary tract whether the kidneys were involved or not; the fever rapidly disappeared and recovery was hastened. In apyrexial infections of the kidney and bladder he employs salol when hexamethylene-tetramine has failed, and is inclined to consider that it is the more beneficial remedy. It appears to be most efficacious against infections due to the colon bacillus, but he has found it valuable in cases of mixed infection of staphylococci, enterococci, and *M. tetragenus* with the colon bacilli. He adds that large doses are necessary and advises a total of 40 to 45 grains in the twenty-four hours, given in cachets of 7½ grains, with a warm drink or at meals. He has encountered very few cases of gastric or intestinal intolerance, and only rarely has the urine become black. He considers that such discoloration of the urine is of no clinical importance.

65. X-Ray Treatment of Diphtheria Carriers.

S. WITHERS, J. E. RANSON, and ETHEL D. HUMPHREYS (*Journ. Amer. Med. Assoc.*, October 16th, 1926, p. 1266) state that the treatment of diphtheria carriers by *x* rays was first mentioned by Witherbee in 1921, and later by Witherbee and Remer in 1922. The method owes its feasibility to the fact that the pharyngeal lymphoid tissue is radio-sensitive. The present authors treated fifty-four diphtheria convalescents and carriers with very well filtered *x* rays generated at an actual voltage of 200,000, corrected to a sea-level reading. All radiation was given at 50 cm. target skin distance and filtered through 0.75 mm. of copper and 1 mm. of aluminium. In no case was more than 60 per cent. of an erythema skin dose given. Only two febrile reactions, simulating acute tonsillitis, occurred. Neither lasted more than a week, and both were in subjects of pulmonary tuberculosis. The applications were usually made at the rate of 50 to 100 milliampere minutes to each side of the head weekly. Twenty-two patients with clinical diphtheria, ten of whom were carriers, became negative in an average of 15.8 days after having been positive for an average of 43.3 days. If those carriers were eliminated who had experimental small doses of *x* rays, and those with a complicating pathological condition were also disregarded, there were left twenty-three carriers, with an average positive culture period of 60.9 days, who became negative within an average of 10.9 days after the first *x*-ray treatment.

66. The Use of Atophan in Ophthalmic Practice.

MAILLARD (*Münch. med. Woch.*, October 29th, 1926, p. 1843) describes the treatment of various eye conditions with the synthetic products atophan and cylotropin. Atophan may be given intramuscularly or intravenously, and in cases with a definite rheumatic diathesis good results have been obtained in the treatment of scleritis, iritis, and iridocyclitis, the pain and inflammation subsiding after the second injection. In cases of uncertain etiology, though improvement occurred, it was not so marked. Injections are given daily or even twice daily if necessary. Cylotropin is said to be a stronger and more irritant remedy; it must be given slowly, and if after-effects such as burning in the upper arm, etc., are experienced, atophan may be substituted. Cylotropin has been tried in all kinds of infection of the eye, perforating wounds, and sympathetic ophthalmia; it must be given very early in the treatment, because when suppuration is well established it is almost useless. Half a grain of the sodium salt, with the same amount of sodium salicylate, is given in 10 c.cm. of water. Cylotropin is a combination containing 40 per cent. of hexamine and 15 per cent. of sodium salicylate; its action is believed to be due to the setting free of small quantities of formaldehyde in the blood.

Disease in Childhood.

67. Infantile Hemiplegia Due to Congenital Syphilis.

L. BABONNEIX (*Arch. de Méd. des Enf.*, October, 1926, p. 561) states that few questions have been so keenly discussed as the relation of infantile hemiplegia to congenital syphilis. While some authorities, such as Fournier, Massol, Savy, and Vaglio, maintain the connexion, others, such as Foerster, Freud, König, Young, and B. Sachs, declare that congenital syphilis does not play any part in the development of infantile hemiplegia. This view is also held by a Scandinavian writer, Nill Silfverskiold, from his study of 91 personal cases of infantile hemiplegia. In 12 out of 38 cases of this condition studied by Babonneix evidence of congenital syphilis was found in the form of bone lesions, perforation of the palate, Argyll Robertson pupil, Hutchinson's teeth, rhagades, and a positive Wassermann reaction. Numerous foreign writers have recorded examples of infantile hemiplegia in children whose parents were obviously syphilitic. In other cases of infantile hemiplegia stigmata of congenital syphilis have been found in life, and characteristic lesions of cerebral arteritis or cerebral gummata, with other lesions of visceral syphilis, have been discovered at the autopsy.

68. Endocarditis in Early Childhood.

P. D. WHITE (*Amer. Journ. Dis. Child.*, October, 1926, p. 536) finds that endocarditis in infancy is rare, and that when it does occur it is usually associated with a "septic" infection. Ten infants under 2 years of age died; in nine the endocarditis was septic in origin, and in one rheumatic. In six of the septic cases physical signs of cardiac involvement were absent during life. Acute articular rheumatism and chorea, very rare in infancy, increase progressively in frequency after the age of 2 years, and there is an associated increase in the incidence of endocarditis. Young children with rheumatic endocarditis rarely die. Clinically there is found the loud systolic murmur of mitral regurgitation, often discovered earlier than the diastolic murmurs of mitral stenosis and of aortic regurgitation. The author emphasizes the importance of careful observation of the condition of the heart during and after every infection in early childhood, since even a slight rise of the temperature above normal, or an unexplained malaise, may indicate endocarditis in a child. White adds that the presence or absence of a family history of rheumatic infections should always be determined; it appears to be of considerable importance.

69. Influenzal Enteritis in Infancy.

S. ROSENBAUM (*Monatsschr. f. Kinderheilk.*, September, 1926, p. 441) states that in the University Children's Clinic at Leipzig 698 infants, aged from 6 to 18 months, were treated for influenza during the triennium 1923 to 1925. Of these, 58, or 8 per cent., showed symptoms of dyspepsia, which could be regarded as parenteral. The total number of cases of dyspepsia during the same period and at the same age amounted to 359, of which 98 were of parenteral origin; so that for every three or four cases of parenteral dyspepsia, six were due to influenzal infection. Infants during the first six months of life were chiefly attacked, 46 of the 58 cases being of this age. In most of the cases symptoms of catarrh occurred simultaneously with diarrhoea, and the diarrhoea was often preceded by vomiting, which was regarded as cerebral in character and as the equivalent of shivering in the adult. Mucus in varying quantities was almost always found in the stools, and not infrequently blood. The duration and severity of the diarrhoea varied. Eight children developed symptoms of toxaemia, and all but one died. Ten died of pneumonia after the diarrhoea had more or less subsided, and one died of convulsions. In three cases the cause of death could not be determined. The total number of deaths amounted to 22. Four possible explanations are given of the involvement of the intestines in catarrhal diseases of the respiratory tract—namely, impaired intestinal function due to the general infection, direct action of the toxin, invasion of the intestinal mucosa by the influenzal organisms through the blood, and ingestion of the influenzal organisms.

70. Cyclic Vomiting in Children.

L. T. LEWALD (*Radiology*, November, 1926, p. 410) reports that in a series of 200 children referred for *x*-ray examination on account of chronic disorders of the digestive tract, one-third gave a history of recurrent vomiting without distinction of sex. In most cases the vomiting was associated with lesions outside the stomach, and it is suggested, therefore, that the term "reflex vomiting" should be applied. In one-fifth of the patients a previous diagnosis of acidosis had been made. The *x*-ray findings usually showed disorder of the colon, which was often much enlarged. Pylorospasm, ptosis,

and dilatation of the stomach were also frequently found, but in very few instances was there any evidence of chronic appendicitis. In one case the vomiting was cured by correcting an internal strabismus. The author considers that cyclic vomiting is not an entity, has no specific cause, and is probably reflex in nature.

Obstetrics and Gynaecology.

71. Osteomalacia and Pregnancy.

G. MORETTI (*Ann. di Ostet. e Ginecol.*, September 30th, 1926, p. 597) describes sixteen cases of osteomalacia which were severe enough to cause deformity of the spine and legs, difficulty in walking, and in some cases bony fractures. The majority of the patients were city dwellers, and all except one were aged from 35 to 45; most of them had had rapidly succeeding pregnancies with abnormally prolonged lactations. Poverty and poor hygienic surroundings were usually reported. In one case only did the symptoms appear during a first pregnancy, and in one instance only was rickets noted in the offspring. The average number of pregnancies which had occurred in these patients was eight; an aggravation of osteomalacia during pregnancy, with improvement afterwards, was frequently reported. Not all of the patients exhibited notable pelvic contraction. The administration of calcium, phosphorus, organically combined iron, and cod-liver oil brought about improvement in some cases, but the most striking benefit was observed to follow castration. This, alone or in combination with Caesarean section, was employed in eight cases, with excellent results in five. Moretti adds that oöphorectomy can only be expected to be successful if performed early; otherwise successive pregnancies lead to permanent bony deformities.

72. Cauterization of the Cervix before Hysterectomy.

B. Z. CASHMAN (*Amer. Journ. Obstet. and Gynecol.*, October, 1926, p. 591) states that cervicitis due to gonorrhoea or secondary to lacerations is so common that in the majority of subtotal hysterectomies a diseased cervix is left behind. In such cases the patient may have leucorrhoea, sacral backache, soreness in the pelvis, and the other symptoms due to the chronic lymphangitis or parametritis which results from cervicitis. Moreover, it has been shown that malignant disease occurs in the remaining cervical stump with greater frequency than was generally supposed. On the other hand, subtotal hysterectomy is a less formidable operation than total hysterectomy; there is less extensive opening of the lymphatic spaces, the vagina is not involved, there is less danger of trauma to the ureters, and the exposure is less difficult. In order to secure the advantages of subtotal hysterectomy and eliminate the disadvantages of leaving behind a diseased cervix, Cashman adopts the following technique in benign conditions of the uterus. The cervix is dilated, the entire cervical canal is cauterized, and deep radical incisions are made at the external os extending well into the vaginal portion of the cervix. In this manner the cone-shaped, gland-bearing portion of the cervix is destroyed by a simple, rapid method. If this is done as the first step in subtotal hysterectomy there is accomplished practically all that is obtained by the total operation, the disadvantages of which are eliminated. As a result of this procedure the cervical mucosa and glands are destroyed, the cervix heals smoothly without a lumen, no after-treatment or dilatation is necessary, and the normal vault of the vagina is preserved. The author states that although the most common point of origin of cervical cancer is in the vaginal portion of the cervix, if the infected cervical mucosa is destroyed the danger of cancer of the cervix is eliminated, for it does not occur in the absence of chronic cervicitis. Cauterization of the cervix also provides a sterile field for cutting across the cervical canal in subtotal hysterectomy.

73. The Menopause and Blood Pressure.

H. LEHFELDT (*Zentralbl. f. Gynäk.*, November 6th, 1926, p. 2889) has investigated 111 cases of natural and artificial menopause to ascertain whether a rise of blood pressure, or variation in blood pressure, or both, should be expected as the result of diminished ovarian activity at that time. In every case a detailed examination was made of the urine and of the circulatory and reproductive systems; renal efficiency tests were not performed, but a detailed history of previous illnesses was taken. The pressure was estimated by the auscultatory method with the patient sitting; it was determined daily when possible. The diastolic pressure showed so little deviation from the normal that only the systolic was considered. The upper limit of the normal systolic pressure was taken to be 140 mm. of mercury, and the first estimation was ignored, being usually much higher than later ones. Of the 111 patients, only 16 had a systolic pressure over 140 mm. of mercury; in 9 of these pathological conditions accounted for the rise, leaving 7 out of the 111 with a raised pressure attributable to the menopause. In view of this small number Lehfeldt considers that while in a few cases the blood pressure may be raised by climacteric conditions, it is unjustifiable to speak of menopausal hypertension. In regard to variations of pressure he examined 56 patients in whom an average number of five estimations had been made. A variation of more than 15 mm. of mercury was considered pathological, and 13, or 23 per cent., showed this, the figures being approximately the same for the natural and artificial menopause. Such variation was twice as frequent in women over 45 years of age and in those with high blood pressure. Of 10 with endocrine disturbances 5 showed variation. From these findings the author concludes that pathological variations occur at the menopause, but they cannot be considered characteristic, since they are found only in a minority of cases and may arise from many other causes. Their recognition is important, as they may give rise to the erroneous idea that there is a permanent increase of pressure.

74. Indications for Vaginal Douching.

ACCORDING to S. R. MEAKER (*Journ. Amer. Med. Assoc.*, October 23rd, 1926, p. 1377) the healthy vagina has no need of artificial cleansing, as its natural acidity and normal bacterial flora maintain proper cleanliness at all times, even after menstruation or coitus. The diseased vagina obviously requires more than mere cleansing, which would be simply palliative. The cleansing douche is, therefore, always either unnecessary or inadequate, and by interfering with the normal bacteriology and chemistry of the vagina it may prove positively dangerous. Leucorrhoea, due to endocervicitis, is the commonest complaint for which medicated douches are used. Since endocervical infections, being deep-seated, are out of reach of any surface application, it follows that the douching is practically useless. Alkaline douches are, however, useful for washing away thick, tenacious mucus, and deodorizing ones may be advisable in cancer or fistula, but as a rule medicated douches are of very limited utility; they often irritate the tissues and set up or maintain a vaginitis. Hydrotherapeutic douches are of three kinds—the cold, the short hot, and the long hot. The cold douche is useful in haemorrhage of non-inflammatory origin, and chiefly in the bleeding from inoperable cancer. The short hot douche has a value in the treatment of pelvic hypoplasia and in the atrophic changes of senility. The long hot or depleting douche is one of the most valuable of minor gynaecological measures, and is indicated in all disorders of which chronic passive congestion is a feature. Meaker insists that, in prescribing douches of any kind, it is important to be specific about details; a douche bag should always be used and not a bulb-syringe, and all douches must be taken in the recumbent position.

75. Contraindications to Posterior Division of the Cervix.

B. SOLOMONS (*Journ. Obstet. and Gynaecol. of the British Empire*, Autumn No., 1926, p. 434) gives a list of the disadvantages associated with the operation of posterior division of the cervix, which has been employed for the treatment of dysmenorrhoea, with or without sterility, when there is stenosis of the cervix with acute anteflexion. He states that a partly unhealed scar is left which provokes marked leucorrhoea, and therefore tends to cause, instead of cure, sterility. He thinks that when pregnancy has followed the operation, thorough dilatation would have led to the same result; he doubts whether the procedure of dilatation was efficiently performed in cases where no benefit followed, while a subsequent operation was successful. He reports a case in which carcinoma occurred in the divided cervix, and, while admitting the rarity of such a catastrophe, states that irritation of the cervix is a predisposing factor to cancer in this position, and that a nulliparous woman is less likely to develop cancer of the cervix if she has not had to undergo this operation.

76. The Menopause and Basal Metabolism.

J. T. KING, jun. (*Bull. Johns Hopkins Hosp.*, November, 1926, p. 281), has studied the basal metabolism of a number of women subsequent to both the normal and artificial menopause, and has arrived at the following conclusions. Pelvic operations upon women, such as bilateral oöphorectomy, unilateral oöphorectomy, and hysterectomy, were found to cause no permanent change in the basal metabolism. The basal metabolism following such operations does not differ appreciably from the figures of normal women under comparable conditions. There is in most patients a tendency to put on weight after complete or partial oöphorectomy. Enlargement of the body surface owing to the deposition of fat is associated with a proportionate increase in basal metabolism. King thinks that deposition of fat after oöphorectomy is not due to alteration of basal metabolism, but probably to reduced vigour.

Pathology.

77. The Suprarenals in Diphtherial Infection.

E. A. MOLINELLI (*Rev. Sud-Amer. de Endocrinol.*, October 15th, 1926, p. 902), as the result of a review of the literature and experiments on mice and dogs, reports that mice for the first twenty days after suprarenalectomy are very sensitive to diphtheria toxin, but in thirty to ninety days after the operation recover or even exceed their previous power of resistance. Dogs which have had their suprarenal medulla excised have the same susceptibility to the toxin as healthy animals. Diphtherial intoxication in the dog does not increase the weight of the suprarenal gland and only produces congestion. The adrenaline content is frequently but not constantly reduced. The quantity of adrenaline secreted is the same in intoxicated as in normal dogs; in some of them it was somewhat greater than in the controls. Stimulation of the splanchnic nerve produced a smaller discharge of adrenaline in profoundly intoxicated dogs than in controls. Injection of nicotine gave rise to a smaller increase of adrenaline secretion in intoxicated dogs than in controls. The severe syndrome of diphtherial intoxication, such as vomiting, asthenia, and hypotension, in the dog cannot be attributed to acute insufficiency of suprarenal adrenaline. Adrenaline or total suprarenal extract is indicated in the treatment of diphtherial intoxication.

78. Pathological Changes in Nerve Tissues due to Hypnotics.

D. L. WOODHOUSE and F. A. PICKWORTH (*Brit. Journ. Exper. Path.*, vol. vii, 1926, p. 325), in association with the late Sir Frederick Mott, investigated the histological and histochemical changes found in the central nervous system of cats and monkeys after the administration of hypnotics of the sulphone and barbitone groups for periods ranging from a few days to several weeks so as to detect recent and cumulative effects. Sulphonal and trional were found to cause marked disturbance of nutrition in growing animals. This was less obvious in the case of the barbitone series, with the exception of luminal. Sleep was not induced in cats by any of the drugs, large doses causing coma, followed by death; in monkeys a condition resembling sleep was produced. In all cases where the hypnotics were continued longer than a week numerous mucinoid particles 5μ to 60μ in diameter were discovered throughout the central nervous system, sometimes within the nerve cells, in staining reactions resembling amyloid. Chromatolysis, loss of the Nissl substance, and signs of degeneration were found in the nerve cells of the cerebellum, mid-brain, and spinal cord after intensive treatment with any of these hypnotics. Many phagocytes were present and appeared to be digesting the nerve cells. The authors believe that this mucinoid substance is a metabolic product of the nerve cells which have been damaged by the hypnotics. It may be a product of ordinary metabolism which under these conditions is not removed or is produced in excess. Further research into the neuro-metabolism is being continued.

79. The Significance of Gastric Anacidity.

C. S. KEEFER and A. L. BLOOMFIELD (*Bull. Johns Hopkins Hosp.*, November, 1926, p. 304) state that certain people who have apparently no serious anatomical disease of the stomach fail to secrete hydrochloric acid after the ingestion of a test meal. In an attempt to ascertain to what extent the various factors which are supposed to influence gastric secretions played a part the authors studied the gastric analyses made on 1,500 general medical patients, 780 of whom were males and 720 females, the ages ranging from 10 to 81 years. These patients were divided into three groups—namely, those with digestive disorders, those with diseases not primarily of the digestive tract, and those presenting no evidence of any anatomical disease. These studies showed that age is a factor, and that the frequency of anacidity increases with advancing years, whether organic disease is present or not. While the incidence of anacidity in patients with organic disease was quite high at all ages there was very little difference in people with organic extragastric disease and in those without any organic disease. Radiograms revealed many variations as regards shape, position, and activity of the stomach, but it was found that anacidity was not associated with any one type of that organ. A ten-minute secretion of less than 10 c.cm. of gastric juice was found to be evidence in favour of organic disease, and one of over 15 c.cm. as presumptive evidence of the absence of gross lesions. Apparently the stomach emptied more quickly in anacidity cases. In testing the *p*H of the gastric secretions the authors used dimethyl as a criterion, and also the reaction to histamine, which, if injected subcutaneously, acts as a powerful stimulant to gastric secretion. Their conclusions are that anacidity to dimethyl after the ordinary test meal does not mean that a complete inability to secrete acid exists, and that *p*H determinations after suitable stimuli are necessary to settle this question. They assert that there is no definite correlation between anacidity and any other factor except age, and that it has not been possible to prove that any digestive symptoms are due to anacidity in itself; that the determination of secretory volume and of *p*H before and after histamine is essential; and that the combination of low secretory volume with complete absence of acid is practically diagnostic of serious organic disease of the stomach, whereas large secretory volumes tend to rule out such disease, with the exception of gastric ulcer.

80. Standardization of Laboratory Tests for Syphilis.

C. M. ANDERSON (*Canadian Med. Assoc. Journ.*, October, 1926, p. 1211) thinks that no laboratory procedure gives more trustworthy information than the Wassermann test when properly performed. He mentions the report in 1918 of the Medical Research Council of Great Britain in which it was stated that there was an urgent need for standardization and that it would be well that one standardized method should receive sole recognition and be alone employed for official returns. Following the lead of this committee several workers in Great Britain and the United States began investigations to find a method which could be accepted as a standard procedure. Kolmer in Philadelphia studied every element which enters into the test. He prepared a highly sensitive and specific antigen and found by experiment the proper proportions of all ingredients to use in the test. His experiments, lasting over a period of six or seven years, resulted in what is now known as Kolmer's standardized technique (*Epitome*, 1925, vol. i, para. 109). This method, after thorough testing and comparison with other methods, has been accepted in many parts of the United States and Canada as the standard test. It has been stated, however, that if a positive Wassermann reaction is due to a changed colloidal condition of the patient's serum, and not to the presence of a mysterious "Wassermann substance," the correct course for the future would seem to lie in simplifying the test for syphilis, and making it a direct test for a particular colloidal condition by perfecting the precipitation tests. Flocculation or precipitation tests as a substitute for the Wassermann reaction have been advocated by Meinicke, Sachs and Georgi, Kahn, and others. Kahn's improved precipitation test has been shown to give results very similar to a reliable complement-fixation test. (See *Epitome*, 1924, vol. i, para. 85.) In a series of 15,100 serums tested by Kolmer's complement-fixation technique and by Kahn's precipitation test in the central laboratory of the Department of Health of Ontario, Anderson found that a very close agreement was obtained in the percentage of the specimens giving definitely positive and negative reactions respectively with each method. There was a less close agreement in the results of the weakly reacting serums. In the small percentage of completely divergent results Anderson found that such discrepancies usually occurred in treated cases, though an occasional untreated case, most frequently in the latent and vascular types of the disease, might show a positive reaction in one test and no reaction in the other. The great reliability of the Kolmer method and the simplicity and apparent reliability of the Kahn precipitation test make this combination, in his opinion, the best standard procedure in the serum diagnosis of syphilis which has yet been devised.

81. Intermittent Infection with Tuberculosis.

J. PARAF (*C. R. Soc. de Biologie*, November 19th, 1926, p. 1182) has tried to determine whether the risk of contracting tuberculosis is greater with continuous or with interrupted infections with tubercle bacilli. To one set of guinea-pigs was given daily 1/1000 mg. of living virulent tubercle bacilli for fifteen days; another set was given the same dose every day for a week, and after an interval of eight to sixteen days the injections were repeated for a week. To each set the same total dose was given; the only difference was that in the first set the injections were continuous, and in the second set there was an interruption. Of 59 guinea-pigs in the second set 52 were dead in three months; of 63 guinea-pigs in the first set only 29 were dead in this time; the remaining 34 died between the third and the sixth month. The method of interrupted injection therefore proved more rapidly fatal than the continuous method. These results are in accordance with those of Grysez and Petit-Dutaillis, who found that repeated but continuous inhalations of the tubercle bacillus were much less dangerous than a single massive inhalation. They agree also with observations made by Bernard and Paraf in clinical medicine. These workers found that it was less harmful to an infant to be continuously exposed to tuberculous infection than to have an intermittent contact with its tuberculous parents.

EPITOME OF CURRENT MEDICAL LITERATURE.

Medicine.

82. Epidemic Encephalitis in China.

M. O. PFISTER (*Caduceus*, August, 1926) reports that epidemic encephalitis is not rare in China. In addition to many cases observed in northern parts of the country he has seen five cases in Hong-Kong within a few months, and presumes that by now encephalitis has spread over the whole country. The disease is stated to have first appeared in China in 1919, the patient being a student, and several small epidemics have been reported since. Though occurring throughout the year a marked rise is noted during the winter months, when the weather is dry and cold, with dusty winds—the season of catarrhs of the respiratory tract. The majority of the patients were between puberty and middle age, and were found amongst people who spent most of their time indoors. Many of the patients were students, but there were very few soldiers, a class which furnishes the greatest supply of neurosyphilitics. The clinical picture resembled that seen in other countries, and the Parkinsonian type represented the largest group, constituting 35 per cent. of the cases. Of purely hyperkinetic forms there were twenty cases. Besides small epidemics of acute cases in Peitaiho, fifteen cases of quite a benign character were recorded in Peking from January to March, 1924. Pfister also states that in five patients attacks of compulsory fixation of the eyeballs were observed, and that the "greasy" face is not a characteristic sign of the Parkinsonian type in the Chinese. Since the first incidence of epidemic encephalitis in China the disease has become milder. Most probably it was introduced from Europe through India to the seaports of southern and eastern China.

83. Relapse of Cerebro-spinal Fever after Cranial Trauma.

L. WEITZEL and L. MARTIN (*Presse Méd.*, September 25th, 1926, p. 1211) record the case of an airman who on the day following a precipitate landing in which he sustained contused wounds of the face developed symptoms of meningitis. Turbid fluid was removed by lumbar puncture, showing a predominance of polymorphonuclear cells and numerous meningococci. Death occurred within twenty-four hours. There was no necropsy, but an operation performed after the accident enabled the authors to exclude fracture of the base. On inquiry into the patient's history it was found that he had had an attack of cerebro-spinal fever accompanied by purpura eleven months previously, which had proved very refractory to repeated injections of antimeningococcal serum. The authors regard the case as an example of a relapse rather than of a second attack of cerebro-spinal fever due to persistence of the meningococcus. They believe this is the first example on record of a rapidly fatal relapse of cerebro-spinal fever due to facial trauma.

84. Intestinal Haemorrhage in Typhoid Fever.

G. HUMBLOT (*Thèses de Lyon*, 1926) states that, according to most writers, intestinal haemorrhage in typhoid fever, the frequency of which ranges from 4 to 10 per cent., is accompanied by an immediate and steep fall of the temperature. According to Humblot, however, whose observations are based on the study of 31 cases, this is very far from being the general rule. In only 37 of the 61 haemorrhages which occurred among his patients was there any fall of temperature, which as a rule was only very slight and did not exceed 0.6°C. The 24 other haemorrhages, on the other hand, were followed by an immediate rise of temperature of 1° C. or more. In some cases the fall of temperature, when it did occur, was not immediate, but was delayed for twenty-four or forty-eight hours after the haemorrhage and was sometimes preceded by a transient rise. In the period following the haemorrhage cases may be divided into (1) indifferent cases, in which the temperature is not affected by the haemorrhage; (2) unfavourable or fatal cases with hyperthermia, less frequently with fall of temperature; and (3) favourable cases in which the temperature falls regularly several degrees in a few days till it reaches normal.

85. Epidemiology of Rubella.

M. HASSELMANN-KAHLERT (*Monatsschr. f. Kinderheilk.*, October, 1926, p. 35) describes an outbreak of rubella in the scarlet fever ward of the children's clinic due to the admission of a wrongly diagnosed case. Eighteen days later a boy, admitted thirty-six days previously with scarlet fever, showed a typical German measles rash with enlarged occipital glands; nineteen days later five other cases appeared, eighteen to twenty days five more, and eighteen days later the last one. There were thus 12 cases in a ward of 20 children; the grade of infectivity was not high as these eight escaped, in seven of whom no history of previous infection could be obtained. Five patients resisted successfully the first exposure to infection but succumbed to the second; in two this lessened resistance was accounted for by attacks of otitis media in between. The outbreak was interesting as providing opportunity for accurate observation. The author considers that it proved that rubella is a definite disease, and also showed the difficulty in distinguishing between its rash and that of scarlet fever. No prodromal symptoms were seen although careful watch was kept. In all cases the auricular and occipital glands were enlarged; there was little general disturbance, only two cases showing any rise of temperature, and no complications were met with. The incubation period was between eighteen and twenty days.

86. The Septic Tank and Protozoa.

J. J. VAN LOGHEM and A. CHARLOTTE RUYS (*Nederl. Tijdschr. v. Geneesk.*, November 13th, 1926, p. 2249), as the result of their observations on the biological processes in a small glass septic tank, came to the following conclusions. The fluid of a properly working septic tank may not only lose the power to destroy pathogenic organisms such as typhoid bacilli, but, even under favourable circumstances, may be extremely slow in recovering this power. The effluent of a septic tank is thus an extremely unsatisfactory fluid from the hygienic standpoint. On the other hand, the tests showed that the activated sludge method deserves more attention. In any case the high oxygen content of sewage so treated favours the presence of protozoa, which play a very important part in the purification of sewage.

87. Cerebral Tumours and Psychoses.

A. GORDON (*Med. Journ. and Record*, November 3rd, 1926, p. 555) observes that while all cerebral changes, gross or fine, may be accompanied by mental disturbance, the evidence is increasing that local brain changes do not act as the primary and sole etiological factor in production of mental disorders, but rather as excitants. He reports eight cases in which somatic symptoms were overshadowed by mental phenomena. A woman, aged 40, with a basal dural endothelioma compressing the left frontal lobe, exhibited temporary mild confusional states, loss of memory, transient exuberance, capriciousness, and olfactory hallucinations. A man, aged 39, with a large cystic mass in the left temporal lobe, compressing the entire left hemisphere, especially the frontal area and the bulbar region, showed symptoms of increased intracranial tension—vertigo, insomnia, headache, concentric contraction of visual fields, especially on the right, without fundal changes, and bilateral deafness. He had marked disorientation, puerilism, confusion, and mild delirium, with illusions of identity. In a case of glioma involving the left supramarginal and angular gyri, the posterior third of the first left temporal convolution, compressing and encroaching on the left frontal lobe, the patient had had bilateral optic neuritis, vomiting, persistent headache and insomnia, with occasional generalized epileptiform convulsions, and manic-depressive symptoms with puerilism. Another patient, aged 50, had two cysts of the right frontal lobe. The patient had had mild left hemiplegia, double optic neuritis, occasional convulsions of the right arm and leg, and occasional severe headache. Manic-depressive symptoms were present, with pronounced euphoria, transient confusion, and disorientation. The patient died in an epileptiform attack. A man, aged 37, with sarcoma in the left sylvian fissure, had suffered from severe headache, double optic neuritis, and one attack of motor aphasia. The patient had frequent maniacal attacks, when he was boisterous, boastful, restless, impatient, and aggressive, with delusions of persecution and visual hallucinations. The intensity of his delusions and his aggressiveness suggested paranoia, while the contracted pupils, increased reflexes, and occasional right extensor plantar reflex suggested general paralysis. A haemorrhagic cyst of the right frontal lobe was found in a patient who had hadsevere paroxysmal headache and vomiting, slight left hemiplegia, and unilateral optic neuritis. There were manic-depressive symptoms with pronounced euphoria, puerility, confusion, and disorientation. The patient died suddenly. It appeared that when manic-depressive symptoms were present the frontal and temporal lobes were particularly involved. Confusion and disorientation were present when the frontal lobe was compressed from a distance. In all cases the frontal lobes were more or less

involved. The author suggests that these cases indicate the possibility of a connexion between the mental symptoms and the cerebral disease associated with or caused by neoplasms, more particularly when the frontal lobes are invaded. On the other hand, many cerebral tumours are unaccompanied by mental disturbance; therefore, this connexion is not absolute, and must be regarded only as a secondary etiological or pathogenetic element. The variations in the clinical pictures, which show a striking difference between the classical psychoses and those associated with cerebral tumours, indicate that the subjacent psychopathic state is constantly being disturbed by the progressive organic disease. Gordon concludes that the psychogenic disturbances are fundamental, while the brain lesions are only contributory to the development of psychoses.

Surgery.

88. Epigastric Hernia.

J. FRIEDENWALD and T. H. MORRISON (*Journ. Amer. Med. Assoc.*, October 30th, 1926, p. 1466) consider epigastric hernia to be more common than is generally thought, and add that the intensity of the symptoms is frequently entirely out of proportion to the physical signs. Since the symptoms often simulate those of other abdominal affections the possibility of an epigastric hernia ought to be borne in mind in the differential diagnosis of gastro-intestinal disorders. Many of these hernias are reducible and disappear in the recumbent posture, and are therefore overlooked when patients with abdominal disorders are examined while lying down. The authors report sixty-five cases, the hernia being reducible in thirty-seven of these. They state that the condition is found mainly in men, is rarely noted before the eighteenth year, and occurs for the most part between the ages of 20 and 50, especially in patients subjected to strain on the abdominal muscles. Two types are recognized, the protrusion in the first being a preperitoneal mass of fat united to the peritoneum by a pedicle, while the second is a true hernial formation, with a canal, a sac, and contents. The first variety is by far the most common and is ordinarily small. The symptoms include local tenderness on pressure, and pain, probably produced by dragging on the falciform ligament of the liver. In about half the cases the symptoms become aggravated and may take the form of intense paroxysmal pain in the epigastrium, especially on exertion, overeating, or after coughing. The pain is frequently associated with loss of appetite, vomiting, flatulence, and constipation, and occasionally with haematemesis and diarrhoea. The radical operation is the best form of treatment, according to the authors, and should be employed unless there is some definite contraindication; post-operative relapses are infrequent.

89. Vesical Calculus in a Child.

L.-D. DOUBRÈRE (*Bull. et Mém. Soc. Nat. de Chir.*, November 17th, 1926, p. 1038), in view of the rarity of vesical calculi in children, records an example of this condition in a boy aged 13. He had been troubled with urinary symptoms for several years, including frequency, pain, and sudden interruption of the flow. A calculus was felt on rectal examination and this was confirmed by a subsequent radiogram. The stone was removed by suprapubic lithotomy owing to its large size and the narrowness of the urethral meatus. The calculus was very friable and broke into pieces during its removal. The bladder was drained, and all progressed satisfactorily for six days, when the boy, during micturition, was seized with sudden pain in the perineum; examination showed that a fragment of calculus was impacted in the urethra. This had to be removed by perineal urethrotomy as it was firmly impacted. The subsequent history was uneventful. The calculus itself measured 5 by 3 cm. and weighed 61 grams.

90. Treatment of Contracture of Lower Extremities.

S. KOFMAN (*Zentralbl. f. Chir.*, November 20th, 1926, p. 2976) discusses means of immobilization and extension in tuberculosis of bones and joints and advocates the use of the plaster-of-Paris bandage. In cases with sinuses and open wounds heliotherapy, though most beneficial, does not correct contractures or prevent their formation. Kofman, therefore, uses sandbags during the sun treatment. In spinal cases the patient lies prone and sandbags are placed on the sacral region, their weight beginning at 5 lb. and increasing gradually. Some improvement soon follows and it becomes possible to stretch the drawn-up legs. The treatment causes no pain or irritation and is easily given; patients become interested, watch their progress, and help to regulate the weight used. It is also suitable in coxitis to correct the bow legs. To straighten flexion contracture and counteract subluxation the patient lies on the back, chaff cushions are put under the heel and just under the head of the fibula, and the sandbag is laid on the knee-joint; if this is sensitive chaff cushions are also placed under the leg. Treatment in this position is more difficult and troubles a sensitive patient more than the first. During the night and when there is no sun the patients wear plaster-of-Paris appliances.

Therapeutics.

91. The Treatment of Hypertension.

R. H. ROSE (*Med. Journ. and Record*, December 1st, 1926, p. 704) reports that in many cases of hypertension, unconnected with Bright's disease and other serious conditions, the diastolic pressure may be reduced 50 per cent. of its advance above 80 mm. and the systolic pressure may also be reduced to the same extent of its rise above 120 mm. After reduction the pressure can generally be maintained at the lower point. The majority of patients were obese, and of middle age, but some were older, even over 70 years. Rose finds that treatment by vaso-dilators does not remove the cause, and recommends strict dieting, endocrine medication, and the treatment of focal infections, including the alimentary tract. Terry has stated that most fat women who seek treatment have hypertension, usually without symptoms of nephritis, diabetes, or syphilis; a high protein, low calorie diet causes a decrease in weight and in blood pressure. Fisk found that it was not uncommon for a fall in blood pressure, 1 mm. per pound, to accompany reduction of weight by diet and exercise. In an analysis of 17,000 life assurance cases Fisk found no preponderance of hypertension among smokers or among those on a high protein diet, but in a group of 2,145 obese patients hypertension occurred in 14.9 per cent., as compared with only 6 per cent. of persons of normal weight. In arterio-sclerosis, with commencing circulatory failure, treatment is contraindicated, since here hypertension is the lesser of two evils, and with reduced pressure cerebral thrombosis or gangrene in a limb might follow. Rose recommends the administration of extracts of the thyroid gland, the corpus luteum, or the ovary, with cathartics containing bile salts or occasional doses of Epsom salts, and a diet consisting chiefly of milk, green vegetables, and fruit. He describes five cases, in which the ages were between 50 and 70. The average reduction in pulse rate was 25, in diastolic pressure 22 mm., in systolic pressure 66 mm., and in weight 11 lb. The results were best in recent cases. Dyspnoea, palpitation, and tinnitus were relieved, and commencing cardiac failure was benefited. No claim is made for reduction in the high blood pressure of Bright's disease, although in some cases albuminuria due to renal congestion disappears.

92. Antitoxin Treatment of Scarlet Fever.

J. F. ANDERSON and G. F. LEONARD (*Amer. Journ. Med. Sci.*, September, 1926, p. 334) state that 130 severe and moderately severe cases of scarlet fever in three institutions in three different States were treated with antitoxin prepared by the immunization of horses with filtered toxin, while 84 mild cases in the same institutions in which no antitoxin was given served as controls. Among the 130 patients, some of whom were very ill with marked toxaemia, no deaths occurred and there were only 4.6 per cent. with complications, none of which were severe or required surgical intervention. No deaths occurred among the 84 mild cases, but 28.6 per cent. had complications and sequels of varying degrees of seriousness, such as severe otitis, mastoiditis, and suppurative cervical adenitis. The authors conclude that a properly prepared and standardized scarlet fever antitoxin is effective in the treatment of scarlet fever, saving life and reducing the severity and frequency of complications.

93. Non-specific Protein Therapy in General Paralysis.

IN a preliminary report, M. M. KUNDE, G. W. HALL, and F. J. GERTY (*Journ. Amer. Med. Assoc.*, October 23rd, 1926, p. 1376) state that the beneficial effect of malarial inoculation in some cases of general paralysis is now well established. The basic theory of von Jauregg, who instituted the treatment, is that the therapeutic benefit is due to the increased temperature resulting from the malarial paroxysm, and this theory is supported by the favourable results reported after subcutaneous injections of tuberculin, the effect of inoculations with the organism of relapsing fever, and the remissions in the nerve [illegible] an
panied by [illegible] ate
available strain of tertian plasmodium, the [illegible]
(from 8 to 12 per cent.) due to malarial treatment, and the method of temperature regulation following the intravenous injection of proteose or typhoid vaccine, led the authors to investigate the effects in general paralysis of intravenous

injections of foreign proteins. Twelve patients with advanced general paralysis received intravenous injections of foreign proteins in quantities sufficient to produce a chill and fever, which resembles the malarial paroxysm, and their improvement was considered sufficient to warrant a preliminary report. The onset of the chill is stated to occur from half an hour to two hours after the injection, and lasts from fifteen to thirty minutes; the temperature reaches its maximum about four hours after the injection, and the fastigium varies from 102° to 104° F. At the onset of the chill a leucopenia is found, followed by a sharp rise, which may reach 30,000 per cubic millimetre from six to eight hours after the injection. The advantages of this method of treatment are that the chills can be produced at will; that the height of the temperature can be approximately controlled by regulating the dose; that the leucocytosis may be of value; and that the patient is not inoculated with a disease-producing organism.

94. Yeast in Pulmonary Tuberculosis.

R. LECOQ and P. FOURNIER (*Bull. Soc. de Thér.*, October, 1926, p. 217) remark that while the necessity of Koch's bacillus in the etiology of tuberculosis is incontestable, the subject must also be susceptible to tuberculous infection, especially as tuberculosis in the adult is usually due to the recrudescence of latent tuberculosis contracted in childhood. In addition to the pulmonary symptoms, considerable importance must be attached to the primary signs of tuberculous infection, which include digestive symptoms, such as anorexia and dyspepsia, and nervous symptoms, such as insomnia and palpitation. In view of the resemblance of the general symptoms of tuberculosis to those found in avitaminosis B the authors have administered vitamin B sensitized by manganese in the form of six pills a day about a quarter of an hour before each meal. In every case the yeast extract had a distinct action on the general nutrition of the patients. A gain in weight resulted without any change in the diet. The yeast extract was found effective in relatively small doses, no further improvement being obtained by increasing the dose to ten pills a day.

95. Administration of Iron to Anaemic Infants.

H. DORLENCOURT and Mme CALUGAREANU-NANDRIS (*C. R. Soc. de Biologie*, October 29th, 1926, p. 1038), as the result of experimental work, conclude that although the elimination of iron by the female mammary gland is normally only about 2.5 mg. per litre of milk, yet it can be increased by administering iron by the mouth. Ten normal women were subjected to a strict dietetic and medical régime, and it was found that the ingestion of iron generally augmented the elimination of this substance by the mammary gland, but that this increase was variable in degree and in the date of its appearance. They recommend that the mothers of anaemic infants should be given ferruginous preparations.

Dermatology.

96. Diaper Dermatitis in Infants.

J. V. COOKE (*Arch. Derm. and Syph.*, November, 1926, p. 539) states that Jacquet, in 1886, distinguished from congenital syphilis, with which it had previously been frequently confused, a dermatitis affecting infants almost exclusively, limited to the diaper area, and consisting of an erythematous papular or papulo-vesicular eruption, frequently with superficial erosions. Cooke adds that this dermatitis is caused by ammonia in the diaper and is therefore a dermatitis venenata. The ammonia is produced in the wet diaper *in situ* by the growth of a saprophytic bacillus (*B. ammoniagenes*) which splits the urinary urea into ammonia. This organism is derived from the intestinal contents, and infects the diaper area as a result of soiling by faeces. The use of diapers dried after impregnating with an antiseptic such as mercuric chloride (1 in 4,000) causes a prompt cessation of ammonia formation and rapid disappearance of the skin lesions.

97. Congenital Ichthyosis.

FRANKENHAUS (*Monatsschr. f. Kinderheilk.*, September, 1926, p. 310), who reports a personal case with a review of the literature, states that the first important work on this subject was published in 1900 by Riecke, who collected fifty-four cases and distinguished the three following groups according to the severity of the attack. The first consists of those cases in which all the symptoms are fully developed at birth, the whole body being covered with thick tough horny shells which may be as much as half a centimetre thick. The hands and feet are generally free, but are often clubbed. Death usually occurs in three days; the longest survival has been nine days. The second group consists of cases in which the symptoms appear in a more or less mild form, one part of the body being affected while the rest escapes. The hands and feet show the same malformation as in the first group, but survival is longer. In the third group the manifestations of the disease are absent or only slight at birth, and do not develop until days, weeks, or months later; survival depends on the severity of the attack. Frankenhaus's case, which belonged to the first group, was a first-born child, who showed not only considerable skin changes, but also marked deformities of the hands, feet, and face. Death, preceded by symptoms of septicaemia, occurred on the fifth day of life, and at the necropsy a well marked hyperaemia of the internal organs was found.

98. Dermatomyositis.

J. S. MCLESTER (*Journ. Amer. Med. Assoc.*, December 11th, 1926, p. 1990) reports a case of dermatomyositis in a woman, aged 50, after a violent attack of tonsillitis. The onset was gradual, both dermatitis and myositis appearing together. The skin manifestations at first closely resembled those of lichen planus; later there was a general dermatitis. The skin of almost the entire body was red, fairly smooth, and markedly thickened, with symmetrical lines of sharp demarcation, along which were vesicles similar to those of lymphangioma circumscriptum. There were also areas of telangiectasis and flat atrophic scars. Several months later, when the acute manifestations had subsided, typical arsenical keratosis appeared in consequence of the administration of much arsenic during treatment; other symptoms included extreme weakness, involving chiefly the legs and arms, pain, with diminution of reflexes, oedema, and contractures at the elbows, with a secondary anaemia of moderate degree and a slight mononucleosis. The author discusses the possibility of a bacterial etiology and mentions the suggestion by Theobald Smith that the disease may be due to the infection of the muscular system by sarcosporidia from an animal such as the pig.

Obstetrics and Gynaecology.

99. Diet in Pregnancy.

L. V. FRIEDMAN (*Boston Med. and Surg. Journ.*, November 25th, 1926, p. 1015), realizing that prolonged labour and undue size of the child probably account for most operative deliveries, reports the results of an attempt to restrict the size of the child, and so shorten the second stage of labour, by limiting the diet of the mother during pregnancy. It was found that a marked decrease in the length of the first stage was also produced, even more constantly. Comparative freedom in diet was permitted unless the weight, taken once a month, showed a greater gain than half a pound a week. A limit of one moderate helping of each dish was advised, and no meals were omitted. If the gain at the end of a month was found to be less than half a pound a week more food was given; if the gain was greater, a strict diet was enjoined, from which all sweets, potato, macaroni, and soups were eliminated, but two tablespoonfuls of cereal food once a day and one slice of bread at each meal were given to guard against acidosis. The patient's weight was then checked weekly and the diet modified as required. An ample calcium and vitamin content was ensured by the use of milk or butter and green vegetables or fruits. Friedman states that patients dieted from the twelfth to the fortieth week of pregnancy, so as not to gain more than half a pound a week, showed less hyperacidity and flatulent discomfort and that there was a marked decrease in the length of the first stage of labour, with coincident diminution in the number of operative deliveries, while the children, being smaller, were less prone to birth injuries. There was also less likelihood of post-partum haemorrhage.

100. Cancer of the Cervix Treated by Radium.

LILIAN K. P. FARRAR (*Surg., Gynecol. and Obstet.*, December, 1926, p. 719) calls attention to the reaction of the tissues to radium in the treatment of cancer of the cervix and the etiological importance of lacerations. At the Women's Hospital in the State of New York all patients treated with radium were encouraged to return for inspection once a month for five years or longer, and the reactions were found to be so nearly uniform that it was possible to predict the appearance of the cervix each month in cases progressing favourably. Five stages were noted: (1) a stage of hyperaemia one week after the initial dose, the carcinoma and adjacent vaginal mucosa being intensely red and hyperaemic; (2) three weeks later the cervix usually showed an extensive green slough, with foul discharge from the broken-down carcinomatous tissue; (3) two months after irradiation the appearance was that of healing, the slough having separated, leaving a smooth, clean, dusky red cervix without any clinical signs

of carcinoma; (4) a month later a stage of contraction caused by the development of connective tissue appeared; (5) the stage of marked contraction seen at subsequent examinations. Occasionally this shrinking of the cervix tightly closes the internal os and is accompanied by abdominal pain and signs of sepsis, which can be immediately relieved by dilatation and the discharge of purulent or bloody fluid. This may have to be repeated in women of the menstruating age. From a study of 300 consecutive histories of cancer of the cervix repeated traumatizations of the cervix by labour or miscarriage appear to exert an important influence upon the occurrence of carcinoma. Careful palpation and visual inspection of every cervix immediately after confinement is advised, with the performance of trachelorrhaphy as a means of lessening the danger of cancer development, and, where this is contraindicated, secondary repair should be effected later.

101. Treatment of Uterine Fibromyomata.

J. C. MASSON (*Journ. Amer. Med. Assoc.*, November 6th, 1926, p. 1530) states that unless a uterine fibromyoma causes dangerous symptoms, discomfort, or possibly sterility, it may not be advisable to treat it. The danger of malignant degeneration is said to be slight, sarcoma developing in about 2 per cent. and carcinoma in about 4 per cent. of cases treated surgically. Masson thinks that radium treatment is advised too frequently, and accounts for many unsatisfactory results. Radiotherapy is indicated for all patients older than 40 who have tumours of less than 15 cm. in diameter with menorrhagia as the principal complaint; in patients under 40 who refuse operation, or if a major operation is considered dangerous; in all cases of uterine fibrosis; and in essential uterine haemorrhage. The indications for surgical treatment are: age less than 40 years; pain or vesical irritability; tumours of more than 15 cm. in diameter; pedunculated or submucous tumours, or those undergoing degeneration or inflammation; tumours other than fibromyomata; and complications necessitating laparotomy. Abdominal myomectomy is said to be the operation of choice for the majority of patients under 40 years; vaginal myomectomy is indicated when the tumour presents through the cervix. Subtotal abdominal hysterectomy should be performed in women under 40 only when it is necessary to remove the greater part of the body of the uterus, and when the cervix is healthy. Total abdominal hysterectomy is best when any lesion other than carcinoma exists in the cervix and laparotomy is advisable, or when the history suggests malignant degeneration in the fibromyoma or an associated malignant condition in the body of the uterus. The author describes the case of a woman, aged 51, with fibroids for which radium had been advised. Menstruation was normal and there was no leucorrhoea. The uterus contained multiple small fibromyomata, and total abdominal hysterectomy with removal of tubes and ovaries was performed. The pathological examination showed numerous fibromyomata, hypertrophied endometrium, cystic cervicitis, multilocular cystic oöphoritis, two epitheliomatous nodules in the left ovary, and another in the fimbriae of the left tube, right chronic salpingitis, and chronic appendicitis. This case illustrates the difficulty of recognizing early malignant disease.

Pathology.

102. Conditional Reflexes in Immunity.

PAVLOV has demonstrated that by combining the showing of food to a dog with the sounding of a gong or rubbing a particular portion of its skin the salivary flow occurred eventually when the gong was sounded or the skin rubbed, in the complete absence of food; such a reflex depending on a conditional stimulus was called a conditional reflex. S. METALNIKOV and V. CHORINE (*Ann. de l'Inst. Pasteur*, November, 1926, p. 893) believe that such reflexes play a part in immunization. Guinea-pigs were given daily intraperitoneal injections of tapioca, *B. anthracoides*, or a staphylococcal filtrate; at the same time a portion of the skin was heated or rubbed. In the peritoneal fluid of these animals a great increase in leucocytes occurred, particularly between the first and third days after the injection, accompanied by a regular change in the differential count. After fifteen to twenty injections the animals were rested for a fortnight. Then, without any fresh injection, the skin was rubbed or heated. Examination of the peritoneal fluid revealed an increase in the number of leucocytes and the characteristic changes in the differential count. Having established the occurrence of a conditional reflex in these animals, they sought to use this in protection experiments. Two guinea-pigs that had received twelve doses of staphylococcal filtrate accompanied by rubbing of the skin were rested for ten days; the skin was then rubbed several times in the usual way. The following day both of them, together with a control animal, were injected intraperitoneally with one-twenty-fifth of an agar slope culture of *V. cholerae*; the control animal died in six hours, but the experimental animals survived. Several other experiments of a similar nature are recorded, and it is concluded that conditional reflexes may play an important part, not only in immunity, but in disease. The authors emphasize the importance, in such conditions as asthma, cardiac troubles, and neuroses, of breaking the patient's habits so as to remove the conditional stimuli which are so effective in precipitating an attack.

103. The Estimation of Indican in the Blood and Urine of Normal Persons.

S. CABRINI (*Il Morgagni*, November 7th, 1926, p. 1409) has estimated the titre of indican in the blood and urine of normal persons, paying special attention to alterations produced by different diets. He withdrew 20 to 40 c.cm. of blood and mixed the serum with an equal quantity of 20 per cent. trichloracetic acid. The precipitate was filtered off, and to every cubic centimetre of the filtrate two drops of a 5 per cent. solution of thymol in alcohol were added. After shaking, and adding 2 c.cm. of Obermeyer's solution, the mixture was allowed to stand for twenty minutes. To extract the colouring matter 2 c.cm. of chloroform were used: the mixture was again shaken, left for four hours, and then examined for the violet colour that is characteristic of a positive reaction. By this technique it is possible to detect as small a quantity of indican as 0.0032 gram. To titrate the amount of indican exactly the serum was diluted in varying proportions, and that dilution which just gave a positive reaction was held to contain the reacting quantity. In testing for indican in the urine a 5 per cent. solution of lead acetate was added in the proportion of 1 part of solution to 4 parts of urine. The mixture was filtered, diluted to the required extent, and the further examination conducted as already described. An examination of five normal women gave the following results: On a milk diet the indican titre of the blood varied from 0.0265 to 0.0533 mg. per 100 c.cm. of blood, giving an average of 0.04 per cent. On Cantani's diet—3 rolls, 2 eggs, 150 grams of meat, and some green vegetables—the indican varied from 0.040 to 0.064 mg. per 100 c.cm. of blood, giving an average of 0.052 per cent. On the ordinary mixed No. 2 hospital diet the indican varied from 0.064 to 0.080 mg. per 100 c.cm. of blood, giving an average of 0.072 per cent. Thus the amount of indican in the blood was least on a milk diet and greatest on a mixed diet. In the urine the amount varied from 0.32 to 6.4 mg. per 100 c.cm. This variation, it will be seen, was very much greater than that in the blood. It was found, moreover, that there was no correlation between the degree of indicanaemia and indicanuria; in many instances the amount of indican in the urine was high when that in the blood was low, and vice versa.

104. The Wassermann Test in Pregnancy.

E. KIENE and A. MAHNERT (*Zentralbl. f. Gynäk.*, November 13th, 1926, p. 2930) have investigated 1,101 patients admitted to their clinics during the first six months of 1926 in pregnancy, labour, or the puerperium, and with or without a history of syphilis. In every case the Wassermann and Meinicke tests were performed. In 79 pregnant women there was delayed haemolysis; 43 of these proved to have syphilis, 36 were doubtful. The serum of pregnant guinea-pigs was found to give seven times the number of positive reactions that serum from male animals did; the authors believe this to be due to the addition of the delaying factor in the blood of the pregnant animals to that of the pregnant woman, and that this proves the presence in serum during gestation of metabolic products giving a non-specific reaction. This was confirmed by the large number of positive reactions found in spring, when the animals of which the serum was used were often pregnant. Allowing for all fallacies 1 per cent. positives remained unexplained, and the authors conclude that in a small number of cases pregnancy causes a rise of the specific or non-specific delaying factor in the serum. They add that in testing for syphilis in pregnant women and after labour the serum required for complement should be taken from non-pregnant animals. Additional precautions are the use of a precipitation test besides the Wassermann; examination before and after labour, since the Wassermann test is often positive before and negative subsequently; and in doubtful cases the cord and placenta should be examined for spirochaetes and vessel changes. Two types of infection of infants are distinguished—namely, that through the placental circulation weeks or months before birth, in which the clinical appearances may be present at birth or appear immediately after, and, secondly, infection occurring during labour via the cord, in which the clinical signs appear only after an incubation period. Two procedures may be necessary to demonstrate syphilis in doubtful cases: repeated neurological tests, and *x*-ray examination before the fourth month, after which the appearances may be confused with those due to rickets or scurvy.

EPITOME OF CURRENT MEDICAL LITERATURE.

Medicine.

105. Myocarditis and Collapse in Typhoid Fever.

DISCUSSING the occurrence of sudden death in typhoid fever R. DE BRUN (*Presse Méd.*, December 1st, 1926, p. 1507) states that the signs of myocarditis in this disease can be divided into two groups—defective tonicity of the cardiac muscle itself, and troubles of rhythm. The muscular changes are the commoner, and comprise a left and often also a right gallop murmur, attenuation followed by disappearance of the first sound, and an embryocardia, which is almost always accompanied by tachycardia. The symptoms of myocardial insufficiency can predominate in one or other of the ventricles. On the left the symptoms are the gallop murmur, signs of bilateral congestion of the bases of the lungs, increase of the cardio-hepatic dullness, a functional mitral murmur, and exceptionally a pulsus alternans; and on the right the disappearance or attenuation of the first sound, the gallop murmur, and a more or less marked cyanosis. Besides sudden death, other dramatic complications ensue in typhoid fever, and the author describes two—the malign syndrome and typhoid collapse. The symptoms of the syndrome are an accelerated irregular pulse, a lowered arterial tension, intense prostration, frequently vomiting, and a green, foetid diarrhoea. The prognosis is usually hopeless, death supervening in five or six days. The collapsus typhosus is signalled by a fall in temperature and in tension, a remarkable alteration in the facies, cyanosis, intense peripheral coldness, tachycardia, and, more rarely, polypnoea. There are two theories as to the pathology of this condition—the cardiac and the bulbar; de Brun inclines to the latter, judging that cardiac insufficiency alone cannot account for the symptoms. He maintains that an impregnation of the bulb involving a paralysing of its different centres with the typhoid toxin occurs, and that this explains the intimate relation between the collapse and sudden death.

106. Arachnidism.

E. BOGEN (*Arch. Int. Med.*, November 15th, 1926, p. 623), who records an illustrative case, states that within recent years fifteen cases of arachnidism, or spider poisoning, have been treated at the Los Angeles General Hospital. All the patients were males, aged from 2 to 65, but more than half were young adults. Most of the cases occurred in the evening or early morning in the summer or early autumn. The spider was located in a water-closet in eleven instances, in a factory once, and in a bed once. In ten patients the bite occurred on the penis, in two on the scrotum, and in two on the back. Bogen remarks that though entomologists and arachnologists are almost unanimous in asserting that spider bites are harmless, the positive coincidence of hundreds of careful observations cannot be disregarded, more than 150 cases of poisonous spider bites having been reported in the United States during the past century. The chief and perhaps the only poisonous spider in the United States appears to be *Latrodectus mactans*, which, in addition to numerous scientific synonyms, such as *Latrodectus formidabilis, perfidus, dodatus, apicalis, variegatus*, and *thoracicus*, and *Theridium verecundum, lineatum*, and *carolinum*, is popularly known as the "black widow," owing to its habit of devouring its mate. The first symptom of arachnidism consists of a stinging sensation, followed within less than half an hour by continuous or intermittent pain spreading from the site of the wound. The final distribution of the pain, however, appears to be uniform and independent of its origin. The other symptoms, in order of frequency, are cold sweats, restlessness, anxiety, dyspnoea, anorexia, nausea, vomiting, constipation, cyanosis, delirium, shock, and acute retention of urine. Tremors, twitching, paralyses, and convulsions have also been noted. In several instances the patient has been operated on by mistake for acute appendicitis or other acute abdominal disease. The acute symptoms usually last six hours or more, and then gradually subside, but complete relief is often not obtained until the end of a week. In 1923 Baerg of Arkansas, whose observations are confirmed by Bogen, found that the bite of *Latrodectus mactans* produced a definite train of symptoms in a white rat, and that immunity was developed after repeated bites. A large number of remedies have been suggested, but no specific treatment has yet been discovered. The clinical symptoms, however, as well as experimental evidence, warrant the acceptance of arachnidism as a true clinical entity.

107. Scarlet Fever Complicated by Peritonitis.

R. E. TAYLOR (*Journ. Amer. Med. Assoc.*, November 6th, 1926, p. 1559), who records a personal case, illustrates the rarity of peritonitis in scarlet fever by the fact that it did not occur among 2,595 cases of scarlet fever observed by Weaver between 1913 and 1922. Platou found eleven cases reported prior to 1924; four of these occurred early in the disease, and seven were secondary to some other complication. Streptococci were found in the peritoneal cavity in seven cases, but there was no report of any bacteriological examination of the blood. Taylor's case occurred in a girl, aged 4, who was admitted to hospital on the seventh day of an attack of scarlet fever with the diagnosis of ruptured appendix. Symptoms of peritonitis had developed four days after subcutaneous injection of scarlet fever antitoxin. Death occurred four hours after admission, and the necropsy showed generalized purulent peritonitis without any perforation of the bowel or gross change in the appendix. Cultures of the heart blood, liver, spleen, and right lung were sterile, while cultures from the left lung and peritoneal fluid contained haemolytic streptococci. The history of the case, the time of onset of the peritoneal symptoms, and the presence of haemolytic streptococci in the peritoneal exudate suggest the possibility of infection of the peritoneum from injection of antitoxin into the abdominal wall.

108. Haemorrhagic Measles Complicated by Encephalitis.

P. A. MCLENDON (*Arch. of Ped.*, August, 1926, p. 544) reports a case of measles in a boy, aged 7 years, who on the fourth day developed frequent tonic convulsions continuing for forty hours. There were marked stupor, hypertonicity, and other symptoms indicating encephalitis; 16.5 cells per cubic millimetre were present in the spinal fluid, which was removed under pressure. The measles eruption was of a purplish hue, with numerous petechial haemorrhages about the neck, chest, and arms. The patient was given two injections of whole blood from convalescent measles cases with an interval of twenty-four hours between each injection. The symptoms rapidly subsided and complete recovery followed.

Surgery.

109. Treatment of Jacksonian Epilepsy.

R. ALESSANDRI (*Bruxelles-Méd.*, November 21st, 1926, p. 103) states that in order to relieve the epileptic attacks it is absolutely indispensable to restore the cranio-cerebral anatomical relations. Although in part the symptoms depend on circulatory disturbances, which connect this disease with common and reflex epilepsy, the local changes, shown particularly by the aura, and the initial local limitation of the convulsions, which only occasionally become generalized, are of supreme importance. The essential cause resides in the local lesion, which acts as an excitant or irritant of neighbouring centres, either directly or indirectly. That action is produced by the formation of a cicatrix, as is seen especially in post-traumatic epilepsy, because the epileptic attacks do not occur immediately, but only when the cicatrix begins to form. Similarly, in cases of Jacksonian epilepsy due to primary cerebral lesions—such as tumours, gummata, tuberculomata, and cysts—the convulsions are relieved by ablation, only to return when a cicatrix is formed. This formation of scar tissue in the thickness of the cerebral substance is inevitable, but it may be reduced to a minimum by replacing the lost tissue by muscle or fat, which also possess useful haemostatic power. But it is particularly important to restore the membranes as far as possible. When this can be done after removal of tumours, scars, or adhesions in post-traumatic or post-operative cases, the results are usually satisfactory, otherwise it is almost certain that the epileptic attacks will return. The author operated on a man for a gumma in the left parietal region. After extirpation he was obliged to plug the wound in order to arrest haemorrhage. The attacks ceased for one month, only to recur with increasing frequency as the cicatricial tissue became consolidated. A second operation was performed for excision of the scar and the patient was relieved for two months with recurrence as before. A third operation was performed; after scar-excision the dura mater was restored with a strip of fascia lata and the bone with an osteo-periosteal strip. Unfortunately the skin covering this strip caused partial necrosis. A fourth operation was undertaken to restore this lacuna in the cranial vault, and ultimately the result was entirely successful. The

patient has had no epileptic attacks since the fourth operation in 1912, and he remains in good health, except for a right spastic hemiparesis. The author believes that this case proves conclusively that anatomical conditions are the most important cause of the Jacksonian syndrome, and that the ablation of scar tissue will produce a definite cure.

110. Ilio-abdominal Amputation.

S. JUDIN (*Surg., Gynecol. and Obstet.*, November, 1926, p. 668) has collected 70 cases, including one under his own care, of ilio-abdominal amputation, which was first introduced by Billroth more than thirty-seven years ago. The operation consists in disarticulation of the bony pelvic ring in front through the symphysis and behind through the sacrosciatic synchondrosis. In the great majority of cases the operation has been performed for sarcoma of the thigh or pelvis and in a few cases for tuberculosis or non-tuberculous osteomyelitis. The high mortality of the operation is shown by the fact that only 16 of the 70 recovered. A large number of patients die either immediately after the operation or as the result of a relapse, or metastasis soon after leaving hospital. Judin, however, thinks that the results may be improved by progress in the technique of the operation, including spinal anaesthesia, nerve-block, ligation of the vessels of the flap, or extension. Judin's case was that of a woman, aged 36, the mother of eight children, on whom the operation was performed under spinal anaesthesia for chondrosarcoma of the femur. Six months after the operation she became pregnant and was delivered of a normal child at full term. The labour and puerperium were normal, and a year later she reported herself in good health.

111. Bloodless Reduction of Long-standing Dislocation of the Lower Jaw.

U. KARELL (*Zentralbl. f. Chir.*, December 11th, 1926, p. 3160) refers to Fink's classification of dislocations of the mandible into the recent, of from one to three days' duration; the intermediate, persisting for a period of from one to three weeks; and the chronic, in which the dislocation has existed for more than three weeks. In such cases Perthes recommends reduction by an open operation. Karell reports the case of a young girl whose lower jaw had been dislocated during the extraction of a carious molar. In spite of daily attempts at reduction, with and without anaesthetics, the dislocation remained unreduced for fifty days, and the patient could not close her lips on account of the displacement of the lower jaw. There was a gap of 2 cm. between the edges of the upper and the lower incisors, and in front of both ears there were projections produced by the dislocated articular surfaces of the mandible. The masseters were very prominent; lateral movements were possible, but with obvious limitation, and the patient had difficulty in swallowing and in articulation. A brief attempt at reduction was made, the patient sitting on a low seat with her head fixed. Continuous increasing pressure was applied on the lower molars, downwards and backwards. After some time the right side was seen to slip backwards slightly, but nothing further occurred. Two hours later another attempt at reduction was made, this time under deeper anaesthesia, the patient lying in the prone position with the head fixed. After prolonged pressure on the molars, combined with firm upward pressure on the chin, the right side was reduced, and with further intermittent manipulation the reduction on the left side was effected. The entire operation lasted forty minutes. Karell recommends that in all cases of long-standing dislocation of the lower jaw similar prolonged conservative manipulation should be employed before resorting to a cutting operating.

112. Vacuolar Osteo-fibrosis.

CHABÉ (*Journ. de Med. de Bordeaux*, December 10th, 1926, p. 915) reports a case of this rather rare disease, which is a variety of Recklinghausen's disease, in a woman, aged 33. The radiogram showed numerous cysts in the femora and a few in the arm and leg bones. One apparent cause in her case was unhealthy surroundings and absence of the sun, for almost complete cure followed in two years from exposure to sunlight. In these cases, Chabé states, acidosis is present and prevents the formation of insoluble calcium salts. The usual symptoms are lightning pains in the limbs, deformity of the bones, bony swellings, spontaneous fracture or after very slight injury, and a fairly wide distribution of the cysts, not excluding the flat bones. The author's case illustrated most of these points. Mikulicz's disease, on the other hand, is characterized by a solitary cyst, confined to the long bones, near the epiphysis, in the period of growth. Moreover, in treatment medical measures may suffice in Recklinghausen's disease, whilst in Mikulicz's disease the treatment is surgical. The distinctive features of Paget's and of Lobstein's disease are detailed also, and a bibliography of the subject is appended.

Therapeutics.

113. A Stable Preparation of Male Fern.

H. BUSQUET (*Paris Méd.*, December 4th, 1926, p. 454) points out that, owing to the inconstant strength of the active principles of male fern, patients treated with this medicament are sometimes given inactive, and sometimes toxic, doses. In the search for a more stable substance, veterinary practitioners were the first to use filicin. This is prepared by titrating the ethereal extract of *Filix mas* with ten times its weight of magnesia. The homogeneous powder produced is decanted and filtered. To the filtrate hydrochloric acid is added; the resulting precipitate, which is dissolved in ether and then dried, is filicin. It is a greyish-red powder, soluble in ether, slightly so in alcohol, but insoluble in water. Filicin is a combination of various acid bodies, and must not be confounded with filicic acid. Its local action is irritant, and if given by the mouth in large doses it causes vomiting and diarrhoea. According to Busquet it is eliminated by the bile. This investigator has studied its action on flatworms and tapeworms, and has found it to be an excellent helminthicide; he states that the ingested filicin reaches the intestine, impregnates the taenia, passes into the blood and then into the bile, and returns to the intestine, where it again acts on the parasites—this cycle being repeated many times. Busquet administers the drug in pills or capsules (in an oil solution) in 12-grain doses for adults; to children he gives three-quarters of a grain for each year of age. He reports that, if given in suitable doses, there are no toxic effects from this drug, that it is of stable composition, and that it exerts a powerful action against the taenia, which are expelled in a few hours. If combined with calomel, both an antihelminthic and a purgative action is obtained.

114. Vaccine Treatment of Whooping-cough.

H. A. N. VECHTMANN (*Nederl. Tijdschr. v. Geneesk.*, October 16th, 1926, p. 1740) relates his observations on 63 children treated with antipertussis vaccine, including four cases in which it was used as a prophylactic; 54 made a rapid recovery. None of the four children given preventive injections contracted whooping-cough, although they were not isolated. The doses ranged from 1,000 million to 3,000 million organisms, with about five days between the injections. Improvement occurred in 7 cases after a single injection, and in 15 cases after two. In 31 cases three injections were sufficient, 11 cases required only two, 15 had four, and 6 needed five. During the last eight months Vechtmann has adopted the plan recommended by Enklaar (*Epitome*, 1926, vol. i, para. 344) of giving a dose of about 3,000 million organisms every other day, with remarkably good results, as of 27 so treated 26 recovered, though one after an initial improvement was not affected; 6 recovered after two injections, 12 after three, 5 after four, and 2 after five.

115. Inefficiency of Skin Antiseptics.

M. B. TINKER and H. B. SUTTON (*Journ. Amer. Med. Assoc.*, October 23rd, 1926, p. 1347) consider that for antisepsis of the skin some degree of penetration is necessary in order to combat the bacteria in the deeper layers of the skin. In the presence of blood the moisture and dilution affect the action of most antiseptics. Serious infections in clean wounds still occur owing to the inefficiency of antiseptics. Laboratory tests have indicated the inefficiency of iodine, and a study of more than 1,550 cultures demonstrated that iodine, trinitrophenol, Harrington's mercuric chloride solution, mercurochrome, and potassium mercuric iodide will not kill most of the resistant and some of the less resistant pathogenic germs, even under conditions of perfect contact. They add that the selective action of antiseptics must be considered, and that the aniline dyes deserve wider use, owing to their germicidal power, penetration, low toxicity, harmlessness to instruments and supplies, and excellent outlining of the field.

116. Auto-haemotherapy.

M. KEMAL and S. SALVATORE (*Il Policlinico*, Sez. Chir., November 15th, 1926, p. 577) describe experiments with the injection of whole blood in phlegmonous inflammation in dogs, and also quote five cases in man similarly treated. From 1 to 30 c.cm. of pure blood are taken from the veins of the elbow and injected directly into the affected part, a special device being employed in the syringe to avoid coagulation of the blood. The authors observed no bad results, and the effect on such inflammatory conditions as boils, phlegmon, and ulcers proved to be decidedly beneficial, improving both the local and general condition. They state that by this means the bactericidal power of the blood is augmented and cure accelerated. Some lymphocytosis is induced and also an increase in the red corpuscles and haemoglobin.

117. The Effect of Sodium Bicarbonate on Gastric Function.

C. S. KEEFER and A. L. BLOOMFIELD (*Bull. Johns Hopkins Hosp.*, December, 1926, p. 379) state that there is considerable disagreement as to the effect of sodium bicarbonate on gastric activity, and that a possible explanation of some of the discordant views may lie in the large size of the dose employed, since very large amounts of soda, in addition to neutralizing the acid, may produce irritative effects. As the result of experiments with test meals to which one or two grams of sodium bicarbonate had been added Keefer and Bloomfield conclude that the introduction of alkali into the stomach causes neither an increase nor a decrease in the volume of gastric juice secreted. The time at which free acid reappeared in the stomach contents after the administration of sodium bicarbonate seemed to depend largely on the emptying time of the stomach; the more rapid the motility (emptying time) the sooner would free acid appear, the volume of secretion being of less importance. No definite changes in motility could be attributed to alkali, which appeared to exercise no effects other than a quantitative neutralization of gastric acid.

Anaesthetics.

118. Prophylaxis of the Complications of Spinal Anaesthesia.

DANIEL (*Bull. Acad. de Méd.*, October 5th, 1926, p. 105) has devised the following method of preventing the shock which occurs after spinal anaesthesia, either at an early stage in the form of cardiac or respiratory syncope and death, or, more commonly, at a later stage in the form of severe and obstinate frontal headache, accompanied by giddiness, nausea, and vomiting, and secondarily by vasomotor changes such as a weak and rapid pulse associated with a high or subnormal temperature. After removal of 5 to 10 c.cm. of spinal fluid by lumbar puncture, and injection of the anaesthetic, the cerebro-spinal fluid is injected intravenously at the bend of the elbow and the operation is commenced five or six minutes later. As the result of his experience of 34 subcutaneous and 66 intravenous injections Daniel came to the following conclusions. (1) After subcutaneous injections the immediate results were generally good, the pulse became rapid in eight or ten minutes and returned to the normal in fifteen to twenty minutes; the respiration remained normal as a general rule, the colour remained good, and there was only some nausea but no vomiting. (2) The late results were also good and none of the symptoms usually following spinal anaesthesia were noted. After intravenous injection the immediate results were still better, and in the great majority of cases the late results were excellent, as out of 66 injected only four had transient headache on the third day. Daniel attributes the benefit obtained to antianaphylaxis, the injection of a small quantity of cerebro-spinal fluid into the blood causing a slight shock which desensitizes the organism for a certain period.

119. Ethylene in Obstetrics.

E. D. PLASS and C. N. SWANSON (*Journ. Amer. Med. Assoc.*, November 20th, 1926, p. 1716) compare the results in the case of 592 patients to whom ethylene-oxygen was given during labour with 300 deliveries under nitrous oxide-oxygen anaesthesia. The same six operators were responsible in all cases, and variations due to individual practices were eliminated by adherence to the same general routine in the delivery rooms. Nurse anaesthetists have given the anaesthetics, using a standard gas machine adapted for ethylene as well as for nitrous oxide. Although no conclusive evidence was obtained the authors believe that ethylene is definitely more rapid than nitrous oxide in the production of anaesthesia. It was found that quite satisfactory obstetric analgesia could be obtained with weaker mixtures of ethylene than of nitrous oxide. A 25 to 50 per cent. ethylene mixture with air was usually sufficient until the presenting part distended the vulva, when higher concentrations became necessary. Three-quarters of all spontaneous deliveries and one-quarter of all operative deliveries were conducted under ethylene alone, whereas with nitrous oxide only about one-quarter of the spontaneous deliveries and only an occasional operative delivery were completed without the addition of ether. The incidence of foetal asphyxia was roughly twice as great under nitrous oxide as under ethylene anaesthesia. In patients who had morphine or pantopon during labour there were twice as many asphyxiated children as when no drugs were given in addition to the anaesthetic. When ethylene was administered by the authors' method the cost was about two-thirds as much per patient per hour as when nitrous oxide was employed. There was a 30 per cent. incidence of nausea or vomiting under ethylene alone, and this was admittedly greater than occurs with nitrous oxide. In their experience the nausea was of very short duration, and vomiting more than once was absent. The addition of ether increased the vomiting incidence in both cases. The authors experienced difficulty with both anaesthetics in the prolongation of the first stage, but with ethylene the use of the weak mixture was advocated as producing analgesia without any noticeable slowing of dilatation. There was no appreciable prolongation of the second stage with either anaesthetic nor any increase in the incidence of post-partum bleeding, but the addition of ether to either agent considerably increased the average bleeding and the incidence of post-partum haemorrhage. Multiparity was a factor in producing excessive bleeding. No explosions occurred in approximately 600 administrations, although the only precaution taken was to earth the metallic parts of the machine. The authors consider that as an anaesthetic for obstetric work ethylene has many advantages over nitrous oxide, and they suggest that it should be used more extensively.

120. Chloroform and Creatin Metabolism.

M. MARONGIU (*Il Policlinico*, December 15th, 1926, p. 619) records the results of a clinical and experimental investigation of the behaviour of creatin bodies after chloroform narcosis and in diseases of the liver and spleen. His conclusions are based on creatinuria seen in patients suffering from echinococcal cysts of the liver after splenectomy for malarial splenomegaly, and after anaesthesia produced by chloroform. He states that creatin originates in the muscles, and that in the normal chemistry of this tissue creatin is discharged from the muscle in a nearly constant ratio, according to the diet and work done. When a toxic cause, such as chloroform, affects a muscle fibre a larger amount of creatin is passed into the circulation. The transformation of creatin into creatinin is effected in the liver. The spleen appears to have no influence on the metabolism of creatin bodies; any such apparent change after splenectomy is due rather to effects on the general and hepatic metabolism than to any direct splenic effect.

121. Spinal Anaesthesia in Genito-Urinary Operations.

H. W. MARTIN and R. ELSIE ARBUTHNOT (*Anesthesia and Analgesia*, October, 1926, p. 261) describe spinal anaesthesia as a root anaesthesia produced by the injection of some anaesthetic agent into the subarachnoid space around the cord, and affecting chiefly the intraspinal segment of the posterior roots in the region where the injection is made. Reviewing more than 6,000 cases in the Los Angeles Hospital, these authors state that the sum of the primary and secondary dangers of spinal anaesthesia for the average case of suprapubic prostatectomy is less than the sum of the primary and secondary dangers from ether administration in the same type of patient. In the 6,000 cases there were only six deaths, four of which would have undoubtedly occurred within a few hours with any anaesthetic, while two were the result of an overdose. The authors conclude that with spinal anaesthesia the fall in blood pressure is greater than with any other method, hence it should not be used in patients with great circulatory hypotension, with myocardial degeneration, or anaemia. Spinal anaesthesia is rendered safer and more generally applicable by being supplemented with a light gas-oxygen anaesthesia. Blood-pressure readings should be taken frequently. Patients as a rule should have a preliminary opiate. Needles should be of small calibre, and loss of spinal fluid should be guarded against as far as possible. If spinal anaesthesia is only used in selected cases and carefully supervised the mortality should be less than 1 in 1,000. The authors add that even if the mortality was 1 in 100 spinal anaesthesia would still be desirable in selected cases because the post-operative mortality directly attributable to inhalation anaesthesia in many prostatics is considerably greater. This form of anaesthesia, when used with discrimination and for special reasons, is most valuable and efficient for operations below the diaphragm where complete muscular relaxation is required.

Obstetrics and Gynaecology.

122. Conservative Treatment of Polypoid Myomata.

V. MAUGERI (*Rev. d'ostet. e gynecol. pratica*, November, 1926, p. 441) describes the case of a woman, aged 33, who after seven months' diminished menstrual losses was pronounced to be pregnant; three months later labour had not occurred and there was considerable pyrexia. After dilatation of the cervix portions of a fibrous substance were removed; another rise of temperature followed and the urine contained albumin and hyaline casts. Further examination showed a large myomatous uterus extending to the umbilicus and containing three large tumours, of which one was presenting through the cervix. After seven days' expectant treatment the general

condition improved until a sudden attack of pain and pyrexia necessitated an intervention in which the polypoid myoma, now occupying the vagina, was removed piecemeal. The second and third myomas led to similar attacks of pain accompanied by pyrexia and morbid renal conditions; vaginal myomectomy had therefore to be repeated on two occasions, respectively three weeks and five months after the first operation. Bimanual findings subsequently became normal. The first acute symptoms occurred within a few months of the commencement of marital relations. Maugeri has also noted vaginal expulsion of a myoma in a woman aged 40 soon after such relations, suspended for three years, had been resumed.

123. Treatment of Impacted Shoulder Presentation.

O. KÜSTNER (*Zentralbl. f. Gynäk.*, November 27th, 1926, p. 3058) contends that in impacted shoulder presentations division of the vertebral column is frequently not only easier but also less dangerous than decapitation. He points out that the tighter the impaction the more difficult is access to the neck, and the greater the danger of causing rupture of the uterus. The most accessible part in advanced cases of impaction is the thorax, and intervention in this region is therefore likely to be least dangerous. For division of the spinal column Küstner recommends the rachiotome, which he described thirty years ago. This resembles the craniocla-t, but has shorter blades, which cut instead of crushing, one being unfenestrated. Before its application the thorax must be opened by the perforator or by a blunt instrument. If the closing of the blades does not completely divide the vertebral column and ribs, this is achieved by closing the screw-clamp which joins the ends of the handles of the ins rument. The rachiotome may now be used to divide the ventral abdominal wall. The lower half of the bisected foetus is extracted first, preferably with the cranioclast.

124. The Foetal Head in Breech Presentations.

P. TRILLAT (*Gynecol. et Obstét.*, 1926, xiv, 4, p. 211) describes an attitude of the foetal head which he has occasionally found in breech presentations; the only illustration in the literature found by him is that by Smellie in 1765. The head is rotated so that the chin approaches the acromion, and inclined so that the parietal eminence approaches the front wall of the thorax and the ear may lie on the sternum. This attitude may persist for several days after birth, when a flattening and atrophy of one cheek as compared with the other may be seen. This a ttude of the head was noted in eight of twenty-four incomplete and one of twelve complete breech presentations; it appeared to be more common in primiparae. Such an attitude of the head in the fundus uteri may have the clinical consequences that diagnosis of the lie of the foetus may be rendered difficult by absence of head ballottement and of the submental sulcus; efforts to perform external version may fail for the reason that flexing pressure on the foetal head is not transmitted to the trunk. In delivery of the after-coming head which has been in the position described there may be difficulty in reaching the mouth, which is situated near the pubis and needs to be drawn backwards.

Pathology.

125. The Haematology of Typhoid Fever.

M. MOREL (*Thèses de Lyon*, 1925–26, No. 97), whose thesis is based on the study of 77 cases of typhoid fever, 36 of which ran a normal course, while 41 showed various complications, comes to the following conclusions. (1) Normal typhoid fever is very often accompanied by more or less intense anaemia, especially at the time of defervescence. (2) Typhoid is not a disease habitually associated with leucopenia, which is only found in prolonged forms at the end of the second month, and is always slight. (3) The lymphocytosis shows a progressive rise from the onset until the end of the disease. (4) The number of moderate-sized mononuclears is much increased throughout the disease, especially at its height. (5) The onset of the disease is marked by a polynucleosis; this is rapidly replaced by a mononucleosis which is sometimes of an extreme degree. Return to the normal is slow. (6) The cosinophils disappear at the onset and reappear at the end of the disease. (7) In normal typhoid fever the haemato-logical formula of a positive blood culture is that of poly-nucleosis. (8) In normal typhoid fever the haematological manifestation of a positive serum test is mononucleosis. (9) Complications give rise to a more marked anaemia, and return of the blood to normal requires more time. (10) Leuco-penia, which is always slight, is more frequent in complicated than in normal cases. (11) Relapses and suppuration produce slight leucocytosis, and myocarditis and nephritis a slight leucopenia. (12) As a general rule the various complications entail a diminution in the number of the lymphocytes and moderate mononucleosis, but do not act on the large mono-nuclears. (13) Relapses, haemorrhages, and pulmonary com-plications are accompanied by polymorphonucleosis, while myocarditis, nephritis, and suppuration give rise to a variable polymorphonuclear reaction. (14) Eosinophils disappear in severe typhoid and reappear at the end of the disease.

126. Relation of Cancer to Nutrition.

Y. FUJIMAKI and M. MASAKI (*Trans. Far Eastern Assoc. Trop. Med.*, 1925, vol. i, p. 943), as the result of experimental work, conclude that a diet free from vitamin A has some relation to the development of carcinoma. They found that when albino rats were fed on such a diet there was thickening and growth of the epithelial cells in the mucous membrane of the stomach, which in some cases proceeded to the formation of carcinoma. While in rats fed on a normal diet the stomach showed no signs of any keratosis, yet in those deprived of vitamin A such a process was usually present. They believe that carcinoma begins in this way, the process continuing with the formation of papillomatous growths succeeded by heterotypical extension, and, finally, by the destructive growth typical of carcinoma. No local injury or irritation was employed. Similar epithelial changes occurred in other organs, including the urinary bladder, kidney, ovary, uterus, and tongue. The authors therefore believe that in experi-mental carcinoma a constitutional predominant cause is present.

127. Pathogenesis of Cancer.

T. J. GLOVER (*Canadian Lancet and Practitioner*, November, 1926) reports the successful treatment of fifty cases of advanced carcinoma by an antitoxin prepared from horses infected with the filter-passing organism isolated by himself. He also discusses the production of carcinomata in rats which have eaten cockroaches infested with a nematode (*Spiroptera neoplastica*), and suggests that the nematodes are the carriers of this specific cancer germ, which probably flourishes in the presence of sugar, as indicated by the fact that the hosts were found to be only those rats and cockroaches which infest sugar refineries and sugar-carrying ships. Glover states that the life-cycle of this organism comprises three microscopically visible stages: (1) the bacillus stage; (2) the spore or coccus-like stage; and (3) the spore-sac stage; in addition to which there is what has been previously described as the filterable phase. Each of these individual stages can be obtained in pure culture, but alterations in the composition or the reaction of the culture medium or in the environment may cause one stage to pass into another. He mentions a test in which the complete agglutination of the antigen occurs in up to 1 in 250,000 dilution, while antigens made from various strains of other pathogenic, and a number of non-pathogenic, organisms, are not agglutinated beyond a 1 in 25 dilution. He describes the method of preparation of a toxin and its standardization, and also a precipitation test. He has found that weak dilutions of the toxin may be used in skin tests to determine susceptibility to, and in some cases the presence of, carcinoma, but adds that further investiga-tion is necessary in this respect. Blood cultures, taken in most of his fifty cases before the antitoxin treatment was begun, showed the specific micro-organism in nearly every instance. After a few injections of antitoxin it was usually found impossible to detect the organism, and in no non-cancerous case was it found. The following clinical con-clusions were reached. Early cases where the disease is local will yield to antitoxin treatment in a large percentage of cases. In more advanced cases where the main growth is surgically removed the metastases will usually disappear with the antitoxin treatment. In cases where the disease is widely disseminated little is to be expected from any form of treatment, although many of the distressing symptoms, such as pain, offensive discharges, and mental confusion and lethargy, are alleviated by the antitoxin. Institutional treatment is desirable.

128. Non-agglutinating Cholera Vibrios.

J. W. TOMB and G. C. MAITRA (*Indian Med. Gaz.*, November, 1926, p. 537) have investigated the non-agglutinating vibrios invariably present in washing tanks during cholera epidemic months, and conclude, as the result of experimental work, that these organisms are identical with the specific cholera vibrios, [illegible] quired temporarily during epidemi [illegible] vibrios are believed to be pathogenic to man, being found in constant association with sporadic cholera. The authors therefore suggest that they constitute the reservoir of endemic cholera in Bengal, being changed in the human intestine into the agglutinating type.

EPITOME OF CURRENT MEDICAL LITERATURE.

Medicine.

129. The Prevention of Serum Disease.

H. HECKSCHER (*Ugeskrift for Laeger*, December 23rd, 1926, pp. 1167 and 1169) gives in two consecutive papers an account from the Blegdams Fever Hospital in Denmark of the incidence of serum disease in connexion with the treatment of diphtheria with large doses of serum, and of experiments in the prevention of this condition. From January 1st, 1924, to April 1st, 1926, there were 1,113 cases of diphtheria treated with serum, this number representing about two-thirds of the total number of the cases of diphtheria in this period. The remaining third required no serum treatment, for the degree of the diphtheria was slight. About 15 per cent. of the serum-treated patients suffered from severe diphtheria, and the doses of serum given were large—that is, 200,000 to 300,000 units, distributed over a period as long as three days in some cases. About nine-tenths of the patients were children under 15 years of age. In 55.6 per cent. there were signs of serum disease, as shown by a rash not limited to the site of injection, pains in the joints and muscles, or fever, or a combination of these symptoms. It was observed that large doses of serum caused serum disease more often than small doses, that the incidence of serum disease increased with the patient's age, that the severity of the serum disease also increased with age, and that, contrary to the observations of others, serum disease was not so frequent after intravenous as after intramuscular injections. The preventive experiments were made with a polyvalent staphylococcal vaccine containing 1,000 million bacteria to the cubic centimetre. For patients over 15 years of age from 0.5 to 5 c.cm. (correspondingly smaller doses being given to patients below this age) were administered by intramuscular injection on five successive days, from the fourth to the ninth day after the injection of the serum. This preventive treatment was given to 193 patients admitted on odd dates between July 25th, 1925, and April 1st, 1926, the 192 patients admitted on the even dates in the same period serving as controls. The patients admitted before this period also served as controls. This preventive treatment appeared to reduce the incidence of serum disease by about a third, the reduction affecting the severe cases almost exclusively.

130. Atypical Lethargic Encephalitis.

J. A. JACKSON and H. V. PIKE (*Med. Journ. and Record*, November 3rd, 1926, p. 569) discuss the difficulty of early recognition of encephalitis lethargica and its multiform clinical symptoms. They record six cases to illustrate the variability of onset and clinical course. A previously healthy girl, aged 6, had a nocturnal epileptiform convulsion, followed by a second one three days later and by others subsequently. Her mental development was arrested, tremors of the hands appeared within three months, and eighteen months after the initial convulsion all the neurological signs of Parkinson's syndrome were present. A woman, aged 50, caught a cold and two days later complained of swelling, pain, and tenderness in the right parotid region, with rapid extension to the opposite side. The temperature ranged between 100° and 102° and the case ran the usual course of mumps. In ten days all local symptoms had subsided, but the temperature did not fall, and the patient became restless, mentally confused, delirious, then somnolent, and finally stuporous. Focal manifestations of cranial nerve involvement appeared—namely, ptosis, partial ophthalmoplegia externa, unequal and irregular pupils, left facial paralysis, and dysphagia, together with general muscular rigidity, fibrillary tremors of trunk muscles, and vesical and rectal incontinence. There was no evidence of meningitis. After three months the patient improved, and in six months she had recovered entirely. A man, aged 22, was awakened by general abdominal pain and vomiting; twelve hours later an operation for appendicitis was advised but declined. After two days the patient appeared to collapse, passing into somnolence, stupor, and finally semi-coma, which persisted for six weeks. He then gradually improved, but did not recover his former strength, while slight right ptosis and right external strabismus appeared. Six months later the syndrome of multiple sclerosis was definite, and included nystagmus, intention tremor, and inco-ordination, increased deep reflexes, a positive Babinski sign, and emotional outbursts. A man, aged 31, had an acute illness lasting six weeks, which was diagnosed as enteric fever. During the third and fourth weeks attacks of maniacal delirium alternated with stupor, but there was no evidence of organic nervous disease. He returned to work but was mentally dull, and complained of pain and weakness in the legs. Within two months he became irritable and impulsive, depressed, and occasionally had hallucinations. Two years later all the signs of paralysis agitans were present and he became bedridden and helpless. A woman, aged 32, suffered from puerperal septicaemia and apparently recovered after several weeks. A few months later she began to have difficulty in walking, tremors appeared in both arms, she became dull and depressed, she was confused, developed hallucinations, and threatened suicide. She was found to have advanced paralysis agitans. A boy, aged 14, had good health except for frequent attacks of tonsillitis. Tonsillectomy was performed, and seven days later, while the throat was still unhealed, he complained of diplopia, headache, and vertigo, and the temperature rose to 102°. Two days later he had a severe convulsion followed by ptosis, right facial paralysis, and nystagmus, but no stupor nor delirium. The temperature fell gradually, and after six weeks the paralysis almost disappeared. He returned to school, but could not learn. His conduct became so bad that he was expelled, and a year later he was certified and admitted to a mental hospital. The authors conclude that the micro-organism of encephalitis lethargica may reach the central nervous system by a variety of channels; the onset of the disease may simulate that of many other diseases. Neurological symptoms may be absent or so slight as to escape attention in the acute stage, and the sequels alone indicate the nature of the disease. All acute general infections should be studied neurologically, the possibility of encephalitis being borne in mind.

131. Angina Pectoris.

S. LA FRANCA (*Arch. di Patol. e Clin. Med.*, Bologna, November, 1926, p. 425) refers to certain cases of angina pectoris where the pain is largely epigastric and accompanied by girdle pains, and he gives diagrams of the usual areas of irradiation. He denies the possibility of angina existing without pain. Attacks coming on in the night, with the patient at rest, may be excited by cerebral activity, as in bad dreams. The diagnosis of cardiac pain of anginal origin is very often difficult, but the existence of dyspnoea, cyanosis, and a small pulse is rather against the attack being purely anginal, while increased blood pressure, bradycardia, and a difference between the axillary and rectal temperatures point to true angina. In tabetic forms of angina the attack usually comes on without any predisposing cause, such as effort or exposure to cold wind. One of the most resistant forms of angina is that associated with aortic stenosis. Its exact etiology is still rather obscure; coronary embolism, arterial spasm, nerve lesions, toxic causes such as tobacco, and cardiac lesions have all been found. The author discusses various explanations of how the pain is produced, especially in relation to coronary embolism, thrombosis, spasm, and aortic disease; he suggests that it is due to dilatation of the artery above a point of occlusion, and to dilatation of the aorta due to increased blood pressure. The nerves transmit and radiate the stimulus according to their degree of susceptibility; some people are more susceptible in this respect than others. During the attack amyl nitrite is recommended for mild cases; trinitrin is slower in its action, but more lasting, and the same applies to erythrol tetranitrate. Morphine and atropine are often necessary. When acute pulmonary oedema or acute cardiac dilatation supervenes bleeding is indicated, with general treatment in the intervals. In surgical treatment the quality of nerve fibre removed seems more important than the extent of removal.

132. Skin Tests in Measles.

R. TUNNICLIFF and R. E. TAYLOR (*Journ. Amer. Med. Assoc.*, September 11th, 1926, p. 846) state that in skin tests with killed cultures of the haemolytic diplococcus associated with measles Tunnicliff obtained positive reactions in 100 per cent. of persons who had not had measles and in only 4 per cent. of those with a history of measles. This intracellular toxin was neutralized in persons with a negative history of measles by convalescent human measles serum, but not by the serum of a person who had not had measles. Ferry and Fisher have recently demonstrated an extracellular toxin in filtered cultures of haemolytic streptococci from measles with which they produce skin reactions in 40 per cent. of persons with a negative history of measles and in only 3 per cent. of persons with a history of measles. Antigens of killed measles diplococci are therefore more effective for susceptibility tests than extracellular toxins.

133. Symptomatology of Headache.

J. L. HALLIDAY (*Glasgow Med. Journ.*, November, 1926, p. 281) discusses the onset, progress, and disappearance of transient headaches and the problem of their production. In forty consecutive cases pressure over the points where cutaneous nerves emerge elicited the fact that one or more tender points were found in every case during the attack round which it centred, and that involvement of the supraorbital nerves, either singly or together, predominated. Many predisposing causes existed, and no one apparent cause was associated with any particular position. Modifications of cutaneous sensibility occurred in the vicinity of these tender points, and in the majority they were in the nature of overaction to painful, and diminished reaction to tactile, stimuli. Intensification of the pain by pressure over other areas occurred, and in one instance pressure over the left mastoid caused a shooting pain over the right forehead. Halliday regards headache as the product of two variable factors—an alteration in the equilibrium of the primary synapses, and the overflowing of impulses from a neighbouring neurone. He considers them analogous to cases of referred pain occurring in such conditions as appendicitis, and differing therefrom only in the ease with which they can be provoked. The frequency of headaches as a symptom is attributed to impulses from cerebral as well as organic causes readily gaining access to the pain tracts of the scalp; the low resistance of the synapses guarding the pain tracts of the ophthalmic division of the trigeminal nerve accounts for the majority of headaches being frontal.

134. Antidiphtherial Immunization by Anatoxin.

J. MEGIAS and F. MORENO DE VEGA (*La Med. Ibera*, December 11th, 1926, p. 533) review the literature and record their observations on 112 subjects who gave a positive Schick reaction and were submitted to active immunization by anatoxin. The ages ranged from 5 to 16 years. Three subcutaneous injections of anatoxin were given on the other side of the arm to the Schick mark, the first dose consisting of 1/2 c.cm. and the next two of 1 c.cm., with eighteen days' interval between the first and second injections, and twenty-one days' interval between the second and third. Two months after the third injection a Schick test was performed on 101 cases, with the following result: 31 boys aged from 5 to 11 had all become Schick-negative, 35 out of 38 boys aged from 10 to 15 had become negative and 3 remained positive, and 31 out of 32 girls aged from 5 to 16 were also negative. The reactions, both local and general, were least marked in small children and most severe in adults. The symptoms were usually slightest after the third injection.

135. Lymphangitis in Pirquet's Reaction.

L. E. HERZFELD (*Monatsschr. f. Kinderheilk.*, October, 1926, p. 48) states that in children with a positive Pirquet reaction there are often not only a papule, but also slightly raised and palpable streaks passing upwards from it 1/2 to 1½ cm. broad and from 5 to 25 cm. long. This lymphangitis is not accompanied by fever or regional lymphadenitis. The lymphangitis appears either with the papule in the Pirquet reaction or a day later, and subsides at the same time as the papule or one or two days earlier. Opinions are divided as to the origin of this lymphangitis. Some, such as Parrhysius, think that the tuberculin has been infected with pyogenic organisms and that these are the cause of the lymphangitis, which is therefore independent of the neighbouring tuberculin reaction. H. Koch, on the other hand, maintains that the lymphangitis is specific—that is to say, is part of the tuberculin reaction—on the following grounds: (1) the lymphangitis occurs only when the cuti-reaction is well marked. (2) Tuberculin only causes lymphangitis in an individual when the Pirquet reaction is intense. (3) Undiluted tuberculin prepared with glycerin and carbolic acid can in all probability be regarded as sterile. Of twelve children with a positive Pirquet reaction observed by Herzfeld only one showed lymphangitis. The tuberculin in all twelve cases was sterile, and Herzfeld attributes the lymphangitis to a definite allergic condition of the organism.

136. Painful Influenzal Nephritis.

Y. GOIA (*Bull. et Mém. Soc. Méd. des Hôp. de Paris*, November 25th, 1926, p. 1599) states that during a small epidemic of influenza at Cluj in Rumania in 1925 renal complications were relatively frequent. In every case the nephritis was manifested by abundant haematuria associated with polyuria. The disease assumed a septic course, with an oscillating temperature and leucocytosis which was sometimes very pronounced. The most remarkable feature, however, was the presence of severe lumbar pain; this Goia attributed to intracapsular tension, and was increased by the occurrence of small emboli and renal congestion. In some cases the pain radiated to the thorax and shoulder, probably owing to the congestion extending to the perirenal tissue.

Surgery.

137. Diagnosis of Biliary Tract Disease.

J. G. MATEER and W. S. HENDERSON (*Arch. Intern. Med.*, December 15th, 1926, p. 708) record the results of an analysis of the diagnostic criteria in chronic biliary tract disease based upon the pathological findings in 94 consecutive operation cases. Recent investigations have shown that cholecystitis is only part of a generalized chronic infection of the biliary tract, there being also a chronic interstitial hepatitis and cholangitis with dilatation of the larger extra-hepatic ducts. Since the relative degree of involvement of the gall bladder, ducts, and liver varies in individual cases it is important to correlate carefully the data obtained from the clinical history and physical examination; from the quantitative serum bilirubin determination, to gain some idea as to the involvement of the liver; from biliary drainage, to detect the earliest stages of bile-duct infection and inflammation; and from cholecystography, to ascertain the pathology and anatomy of the gall bladder. By such methods disease of the biliary tract may be discovered in its early stages. Duodeno-biliary drainage has been used extensively as a diagnostic and also as a therapeutic measure, the significant microscopic findings being bile-stained clumps of pus cells and bacteria and cholesterin or calcium crystals. The authors have used cholecystography in examining 590 patients, the dye being given by the mouth in gelatin capsules previously exposed to formaldehyde fumes for six hours to ensure their more prompt digestion in the intestine. Each capsule contained half a gram of sodium tetraiodophenolphthalein emulsified in olive oil, 0.06 gram per kilogram of body weight being given, with minimum and maximum doses of 2.5 and 5.5 grams respectively. Failure to define the gall bladder or persistent faintness of its shadow with delayed emptying are the most suggestive signs of indirect diagnostic value, while negative gall-stone shadows and angular irregularity in the gall-bladder contour shadow are of direct value in diagnosis. The authors found that cholecystography afforded correct evidence of the presence of chronic gall-bladder disease in 89.1 per cent. of a group of 64 cases coming to operation. In duodeno-biliary drainage direct evidence of chronic cholangitis, with indirect evidence of cholecystitis, is afforded by the finding of bile-stained clumps of pus cells and colonies of bacteria, while showers of clumped crystals in the bile strongly suggest gall stones.

138. Malignant Degeneration of Hypertrophied Prostate.

DE BROECK (*Le Scalpel*, December 25th, 1925, p. 1062) reports the case of a patient, aged 65, with prostatic hypertrophy, in whom the only symptoms were pain, sometimes at the beginning, sometimes at the end of micturition, with difficulty of emission. The urine was cloudy, but gave negative cultures. The sound showed a stricture present in the posterior third of the urethra, and progressive dilatation was prescribed. The right lobe of the prostate was hard, but the left was soft and delimitable. The sign of Chevassu was negative, and on cystoscopy the bladder, with a capacity of 150 c.cm., appeared normal except at the lowest part, which was red and raised, hiding the ureteral orifices. Fifteen days later, as examination showed the right lobe to be increased in size and the Chevassu sign became clearly positive, prostatectomy was successfully performed, the gland being easily enucleated, except at the floor of the bladder where there were adhesions due to an adenoma. The patient made an uneventful recovery. The growth proved to be a papilliferous cysto-adenoma undergoing malignant degeneration. The author adds that by tactile examination he was able to follow the evolution in a few months of a prostatic hypertrophy into a malignant tumour.

139. Haemorrhoidectomy.

J. M. LYNCH (*Amer. Journ. Surg.*, November, 1926, p. 245) finds that discomfort after haemorrhoidectomy may be due to a tight sphincter, divulsion preceding operation, rough handling of the tissues, plugging, and the habit of confining the bowels. If the sphincter is found to be tight before operation cutting it is the only method that will relieve pain. He considers divulsion bad surgery. Local infection is often a cause of pain after operation; it is due to damage of the tissues, and can be avoided by gentleness. Packing is unnecessary and should be avoided, while the bowels may be safely opened forty-eight hours after operation. Lynch thinks that some form of ligature operation, under local anaesthesia, is the most satisfactory. With the patient lying in Sims's position the piles are seized in artery forceps, withdrawn, and ligatured; if the sphincter is tight it is divided in the posterior commissure. The stay in hospital after operation ranges from three to five days.

140. Renal Tumours.

R. BRETSCHNEIDER (*Zentralbl. f. Gynäk.*, December 4th, 1926, p. 3134) reports two cases of renal tumour, and discusses the possible difficulties of diagnosis. If the three cardinal symptoms—intermittent haematuria, palpable tumour, and pain—are present, the diagnosis is relatively easy. If one is absent, especially the haematuria or tumour, it may be extremely difficult, and Bretschneider strongly recommends ureteral catheterization and the renal efficiency test. In the past many renal tumours without haematuria were thought to arise from the ovary, spleen, gall bladder, or bowel, and the operating surgeon has been sometimes obliged to remove one kidney without knowledge of the functioning capacity of the other. The author finds that fever occurs fairly early; it is usually intermittent and is found, according to Israel, in 8 per cent. of the cases. Diarrhoea may alternate with constipation, or be absent even in presence of a large tumour, suggesting that the causation is not purely mechanical; Bretschneider thinks it may be of endocrine origin, and due to the close connexion between a hypernephroma and the suprarenal gland. Although some renal tumours are apparently innocent, the great majority are fatal sooner or later. Early operation is advisable, and in doubtful cases a laparotomy should be performed for investigation. Should operation on a hypernephroma be delayed, or not sufficiently thorough, widespread and rapidly growing metastases will appear and hasten the fatal termination. With early operation the prognosis is fair; of Israel's 124 cases 25 per cent. were alive after five years. Few cases treated by *x* rays have been reported yet, but among these good results were obtained in a sarcoma and a hypernephroma. Bretschneider thinks it should be tried in inoperable cases, and after operation to prevent recurrence.

141. Primary Tuberculosis of the Parotid.

F. LAZZARINI (*Il Policlinico*, Sez. Chir., November 15th, 1926, p. 565) reports a case of this rare affection in a girl aged 17; there was no history of tubercle in the family. The author discusses the various theories as to the mode of entrance of the bacillus in these cases, and gives a photograph of the histological appearance of the growth removed from this patient. In this case it took the form of an isolated mass, interfering slightly with mastication, painless, and with the overlying skin unaffected; it was excised, and on section proved to be tuberculous. The author refers to twenty-two similar cases of primary tuberculosis without signs of tubercle elsewhere. The isolated type is not so common as a generalized disseminated affection, with or without fistulae. Age, sex, and heredity seem to play no important part in the etiology of these cases. The treatment is surgical, by excision, aspiration, or scraping, and the prognosis is good.

142. Lumbar Pain as the First Sign of Mammary Cancer.

E. LIEK (*Zentralbl. f. Chir.*, December 18th, 1926, p. 3212) describes the case of a woman, aged 36, who had been incapacitated for a month by severe pain in the lumbar region which defied all treatment. Liek was at first unable to find any evidence of pathological change, and skiagrams were also negative. Four weeks later the pain had increased, and Liek then detected a projection of the right nipple, caused by a scirrhus as large as a walnut. The patient died five months later, a very early metastasis in a lumbar vertebra being demonstrable by a skiagram. Liek has seen two other cases of lumbar pain for which no cause could be found until a mammary carcinoma was discovered; he observes that such occurrences show the necessity of a most thorough physical examination.

143. Double Penis.

C. BRUNI (*Arch. Ital. di Otol.*, October, 1926, p. 143), who records an illustrative case, states that while anomalies of the genito-urinary system are frequent, cases of double penis with a double urethra are very rare. The first case was seen in a cadaver at Bologna by I. I. Wecker in 1609. Ballantyne, in 1895, collected thirteen cases from the literature, and Bruni has found three more, making a total of sixteen. Bruni's case was that of a man, apparently about 35 years of age, who was found dead in the street. Nothing could be learnt as to his past history in general or his sexual life in particular. The body showed two penes, with one half of the scrotum containing a testicle beneath each. The meatus and urethra of each were normal. On opening the body the kidneys were in the normal position, but the ureters were connected with two distinct bladders. A prostate was present on each side. The pelvic portion of the rectum bifurcated into two distinct portions, each of which opened by an anal aperture behind each half of the scrotum.

Therapeutics.

144. Iodine in Goitre.

D. GUTHRIE (*Therap. Gazette*, December 15th, 1926, p. 837) believes that many goitre patients are injured by the incorrect use of iodine in treatment. While iodine in small amounts will prevent the developme[illegible] goitre of adolescence, and in a certa[illegible] effect a cure, it is important that [illegible] under observation during treatment. He considers it unsafe to give iodine after the age of 25 because the glands may contain small adenomata which may be rendered active thereby. This applies also to the chronic rounded goitre, since these quiescent adenomatous goitres are rendered toxic by iodine, which should not be given to any adenomatous goitre patient who is already toxic. Such conditions are essentially surgical if the patient's condition sanctions an operation. In exophthalmic goitre treatment by iodine is not curative, but may be useful in preparation for operation; during its administration the patient should be in hospital so that repeated metabolism readings may be taken, and the patient prepared by the administration of Lugol's solution, which lessens the need for stage operations and reduces the mortality and morbidity of the disease. Guthrie considers that the public should be warned of the great danger which attends the self-administration of iodine in the treatment of goitre, and that physicians should recognize the types which are suitable or unsuitable for such treatment.

145. Vaccine Treatment of Urinary Infections.

M. LARGET, J.-P. LAMARE, and E. MOREAU (*Presse méd.*, December 15th, 1926, p. 1571) state that *B. coli* being polymorphous and of variable virulence, it is often difficult to use stock vaccines with any assurance of success. They recommend, therefore, the use of autogenous vaccines and auto-filtrates in the treatment of urinary infections with this bacillus. They describe in detail their technique in preparing the vaccines and filtrates, and their routine of treatment is as follows. The urine is obtained aseptically by catheterization, and a cytological and bacteriological examination made. A vaccine is prepared containing 500 million organisms in each cubic centimetre. An initial dose of half a cubic centimetre is given at once, followed at intervals of two days by 1 c.cm., 1½ c.cm., and 2 c.cm. The authors also employed weekly irrigations of both kidney pelves with bacillary filtrate, ending each irrigation with an intravesical injection, which the patient retained as long as possible. The results were watched and controlled by repeated cultural examinations. No reactions have occurred after the use of either the vaccine or the filtrate. The authors claim to have obtained excellent results from this method in both acute and chronic urinary infections, but advise dietetic and alimentary medication during the course of treatment, and lay stress on the method of preparing the vaccine, as this plays an important part in the success of the treatment.

146. Treatment of Infantile Tetany.

J. P. SCOTT and S. J. USHER (*Journ. Amer. Med. Assoc.*, December 4th, 1926, p. 1904) report a series of twenty-one cases of infantile tetany treated in various ways. Calcium chloride was given by the mouth to nine infants, in 15 grain doses for three hours, with rapid improvement. In three cases ammonium chloride was given by the mouth in 7 grain doses, with similar benefit as regards the symptoms. In one case, when the calcium chloride was discontinued for a day convulsions reappeared and the signs of latent tetany were found present, even after several weeks' administration of either salt. As a rule the blood calcium content was raised, but in two cases there was a definite decrease. Frequent treatments with the mercury vapour quartz lamp were found to give the most rapid and most permanent results in raising the calcium content, and both the tetany and accompanying rickets were cured. The authors add that infantile tetany may occur with a blood calcium content within the normal range.

147. Novarsenobenzol in Lupus Erythematosus.

P. RAVAUT and BOCAGE (*Ann. de Derm. et de Syph.*, December, 1926, p. 657) report their results of treating lupus erythematosus by intravenous injections of novarsenobenzol. The treatment is based on the idea that at the back of many cases of this disease there is a syphilitic taint, usually hereditary, and that syphilis, though not the sole cause, acts by preparing the soil for the development of lupus, as it may do in other tuberculous lesions. Of the 23 cases treated, in 7 the lupus completely disappeared, in 4 almost completely, in 4 there was marked improvement, and in 2, where the disease was situated in the hair and was thus difficult to cure, no good results were observed. In the other 6 cases treatment had

to be abandoned because of unpleasant sequelae. The average dose given once a week was 45 cg. Rather troublesome reactions were occasionally seen, such as congestion, nausea, salivation, cough, cyanosis, headache, and insomnia, either immediately after injection or two or three hours later. As a rule the reactions were only transient; cyanosis or loss of consciousness contraindicates further treatment. The authors find that this intolerance may be lessened by the simultaneous injection of glucose and sodium hyposulphite. At least ten or twelve injections are needed, and as a rule no improvement is noted until about the fifth injection. In 22 cases the Wassermann reaction was positive eight times.

148. Treatment of Insomnia.

J. B. LOGRE (*Bull. Soc. de Thér.*, December 8th, 1926, p. 255) distinguishes four groups of insomnia: symptomatic, constitutional, intermittent, and the insomnia in febrile disorders. In symptomatic insomnia the causal disease must be discovered and treated; in this, as in all the other groups, the hypnotic is not the best treatment of insomnia, but merely a makeshift to be used only when all the known causes of insomnia have been excluded. The principal causes of an apparently isolated insomnia are gastric disease, puberty, in which pituitary medication is often useful, the menopause, for which thyro-ovarian treatment is indicated, disturbance of arterial tension, and latent infections, such as appendicitis, osteomyelitis, or syphilis. In constitutional insomnia drug treatment is of secondary importance, and more attention should be paid to physical and moral hygiene, physiotherapy, ultra-violet rays, and psychotherapy. In intermittent insomnia treatment of any kind is almost always unsuccessful, and in febrile diseases only small doses of hypnotics should be given, as otherwise the action of the drug combines with the infection to produce dream delirium.

149. Diathermy in Gonorrhoeal Endocervicitis.

B. C. CORBUS and V. J. O'CONOR (*Journ. Amer. Med. Assoc.*, November 27th, 1926, p. 1816) consider diathermy to be a valuable method of eliminating endocervical gonorrhoea. They state that the persistence of gonorrhoea in women is mainly due to the presence of the gonococcus in the paraurethral, cervical, and endocervical glands, and that treatment should aim at destroying the organisms *in situ* without causing any permanent injury to the endocervical canal. Since the gonococcus is instantly destroyed at 113° F., or at 104° F. prolonged for six or eight hours, while normal epithelial cells can resist 118° F. for an hour, the rationale of destroying the gonococcus within the living tissues is obvious. The clinical application of diathermy provides a means of obtaining the effect of regulated, deep-seated, localized heat on metabolism and the specific action of heat on the gonococcus. Cure will depend upon the use of a high-frequency machine delivering the proper current through properly designed and adjusted active and inactive electrodes, the time of application being controlled by thermometer readings. Details of such a machine and electrodes are described. It is added that treatment must be continued until the gonococcus can be proved to have been eliminated from the tissues. The authors are fully satisfied with the clinical results obtained by careful application of diathermy during a period of over six years in approximately 150 cases.

Radiology.

150. Radiographical Diagnosis of Aortic Regurgitation.

G. W. HOLMES (*Brit. Journ. Radiol.*, November, 1926, p. 409) reports the results of *x*-ray examination of thirty-four cases of aortic regurgitation of doubtful etiology. The method was found particularly valuable in distinguishing syphilitic from rheumatic cases. Diagnosis was based on the shape of the heart shadow and the presence or absence of aortic dilatation. Holmes states that in uncomplicated aortic regurgitation the curve of the left ventricle is rounded, the apex is blunt, the left axis approaches the horizontal, and the pulsations of the left ventricle are distinct. Increase in size varies in degree, but is always to the left. With involvement of other valves or auricular dilatation there is a general increase in the size of the heart, and *x* rays become less helpful. Increase in the transverse diameter of the aortic shadow may be due to syphilitic aortitis, hypertensive heart disease, arteriosclerosis, or an unusually high diaphragm. In syphilitic aortic regurgitation there is increase in the supracardiac dulness, abnormal pulsations in the region of the aortic valve, a cone-shaped supracardiac shadow, a flattened aortic knob, pyramidal shadows extending from the heart in the region of the innominate and subclavian arteries, and slight general enlargement of the heart's shadow, or marked enlargement of the left side of the heart with a blunt apex and horizontal position.

151. Indications for the Static Electric Current.

THE treatment of various forms of inflammation by the static electric current is recommended by W. B. SNOW (*Med. Journ. and Record*, December, 1926, p. 769), who traces its usefulness to the fact that, being a direct or constant current of high potential, it possesses the power of inducing contraction of the muscle cells. It aids in the mechanical removal of infiltration from engorged tissues where no infection is present, and relieves tense muscles by overcoming the contraction associated with inflammation; it also improves local and general metabolism. Snow has treated many hundred cases of prostatitis in this way, and believes that surgical treatment could be obviated very often by the early employment of the static current. Similar benefit is obtainable in other pelvic conditions, such as dysmenorrhoea, uterine congestion, subinvolution, and vaginismus, while visceral congestion, not associated with local infection or malignancy, also responds well. Other conditions treated successfully include exophthalmic goitre, arthritis, poliomyelitis, sciatica, and neuritis. The good effect on general metabolism from the active passage of the current through the body during its administration has often been found to be remarkable.

152. X-ray Treatment of Malarial Spleens.

P. HEYMANN (*Journ. de Radiol. et d'Electrol.*, November, 1926, p. 481) distinguishes two types of malarial spleens—the acute and the chronic. In the acute type, which follows a recent infection, the increase in the size of the organ is relatively small, the principal lesion being a general congestion of the adenoid elements; in the chronic, due to a slow infection of long duration, the spleen is much enlarged, often reaching down to the umbilicus and invading the left hypochondrium. In these chronic spleens there is, besides a congestion of the Malpighian follicles, a hypertrophic sclerosis, not only of the pulp, but also of the follicular portion. Failure to distinguish these two types is the cause of the failures experienced in radiotherapy. The author reports sixteen cases of malarial splenomegaly treated by *x* rays, and describes the treatment in each of the three groups into which he divided the cases. His findings were that in acute cases there was a complete regression, due to the influence of the rays on the lymphoid tissue, but in the chronic this diminution in size was only partial, the Malpighian follicles being affected by the rays, while the greater part of the spleen, being composed of fibrous tissue, was unaffected. In conclusion, Heymann states that radiotherapy in certain acute cases is efficacious, but that it does not produce a complete amelioration in chronic ones where a profound fibrous infiltration renders the tumour insensible to the action of *x* rays. He claims that the length of the treatment, its difficulties and inconveniences, are sufficient grounds for rejecting it in the treatment of malarial spleens, that acute cases regress spontaneously, or with the aid of quinine and arsenic treatment, and that chronic cases are best relieved by surgery.

153. Radium Treatment of Diseased Tonsils.

J. C. SCAL (*Med. Journ. and Record*, December 1st, 1926, p. 673) describes the treatment of tonsillar hypertrophy by removable platinum radon seeds on the lines suggested by Joseph Muir of New York. Using a special implanter, which is illustrated and described, the pain of insertion and removal is practically nothing. No anaesthetic is required, and no disability or shock results. The radon seed is planted in the middle of the tonsil and the rays are filtered by 0.3 mm. of platinum, which cuts off the caustic beta rays, so avoiding burning, necrosis, and sloughing. When the implanter is withdrawn the seed is left embedded with a short length of thread protruding from the opening; at the end of four days the seeds are easily removed by pulling on the thread. The author states that in this way the amount of radiation can be accurately measured and complete distribution effected. Only one treatment is necessary. He believes that this procedure affords an adequate substitute for tonsillectomy in cases where surgical treatment is contraindicated.

154. Iodized Oil in Bronchiectasis.

B. WHYTE (*Canadian Med. Assoc. Journ.*, December, 1926, p. 1443), from an experience of 150 cases, recommends the use of iodized oil in bronchiectasis as a means of ascertaining the extent and size of the bronchial dilatations and for treatment. Its diagnostic value in endobronchial injection lies in its fluidity, opacity to *x* rays, tolerance by the bronchial mucous membrane, and the comparative ease of its administration by the supraglottic method, 15 c.cm. of the oil being injected into the glottis in thirty seconds by means of a laryngeal syringe. The soft palate and posterior portion of the tongue are previously anaesthetized with a 5 per cent. solution of butyn or 10 per cent. cocaine, and the patient breathes slowly and rather more deeply than normally. The oil having a specific gravity of 1,350 its deposition in the

bronchi can be largely controlled by posture, the initial injection being made with the patient seated. Inclination of the body to the right, or forwards, or backwards will allow the oil to run into the right bronchi or the anterior or posterior branches as desired. For injection into the middle and ascending bronchi the patient should be lying on a tilting table with the desired side downwards. The intervals between the injections varied from five to fourteen days, and the duration of the treatment depends upon the tenacity of the symptoms. Thirteen patients treated by iodized oil were improved, and Whyte advocates the supraglottic method of injection because it is easy for both patient and operator, is brief in duration, requires only a small amount of local anaesthetic, and it answers the requirements of both diagnosis and treatment. The procedure should be avoided in conditions of acute pulmonary disease, cardiac decompensation, or in cachexia.

Obstetrics and Gynaecology.

155. Bandl's Ring as a Cause of Dystocia and Foetal Death.

H. H. SCHMID (*Zentralbl. f. Gynäk.*, October 23rd, 1926, p. 2760) relates the case of a 2-para, aged 26, whose first pregnancy had been terminated by perforation of the living child. After being forty-eight hours in labour she was prepared for Caesarean section, which was abandoned owing to death of the foetus. Vaginal examination, now made for the first time, showed almost complete dilatation of the os, an intact amniotic sac, and presentation of the vertex, together with a pulseless loop of the cord. Uterine exploration demonstrated compression of the cord between the breech and Bandl's ring, which was situated two fingerbreadths below the umbilicus. Delivery was completed by rupture of the membranes, version, and perforation and extraction of the after-coming head; a small degree of pelvic contraction was present. Bandl's ring in this case is regarded as purely a contraction ring; retraction was absent, as shown by the complete relaxation of the corpus uteri and the lower uterine segment between the pains, the absence of tension in the round ligaments and of tenderness in the lower uterine segment, the ease with which version was done, and the occurrence of five-minute intervals between the uterine contractions. The case is noteworthy in that Bandl's ring was perceived before intrauterine or even vaginal examination had been made. Quinine had been given five hours before delivery, but Schmid regards the case as an example of non-traumatic, possibly physiological, ring contraction, for which, if recognized before death of the foetus, Caesarean section is the ideal treatment.

156. Premature Detachment of the Normally Situated Placenta.

L. PRAGER (*Tidsskrift for den Norske Laegeforening*, December 15th, 1926, p. 1169) reports from the University Maternity Hospital in Oslo 50 cases of premature detachment of the normally situated placenta. The period covered was the last five years, during which there were about 8,000 confinements. There were 39 multiparae to 11 primiparae, and only in 16 cases was the urine free from albumin. Labour terminated spontaneously in 34 cases; in the remainder it was hastened artificially, vaginal Caesarean section being performed twice and abdominal Caesarean section four times. Four of the mothers died, both of the cases of vaginal Caesarean section terminating fatally. The infant mortality was 62 per cent. Only in 10 cases did the confinement occur at term; in 4 cases the pregnancy went beyond term, and in the remaining cases the pregnancy had not reached term when this accident happened. Discussing its frequency and diagnosis, the author states that before 1905 it was hardly ever diagnosed at the Maternity Hospital. Between 1905 and 1914 its incidence was 0.16 per cent., by 1921 it had risen to 0.5 per cent., and by 1926 to 0.6 per cent. The same evolution has been observed in the Rotunda Hospital in Dublin, where the incidence of this condition has risen from nothing some time ago to 0.74 per cent. Yet the clinical picture is well defined, and the diagnosis so easy, provided the condition is remembered, that midwives trained at the Maternity Hospital in Oslo make this diagnosis in private practice and send their patients forthwith to hospital. The symptoms which the author considers characteristic in a typical case are: (1) sudden pain in the lower abdomen; (2) internal or external haemorrhage, or both, with signs of anaemia; (3) hardness, enlargement, and tenderness of the uterus; (4) absence of labour pains at first, and, when labour has begun, imperfect differentiation of contraction and relaxation. The placenta is born immediately after the infant, together with numerous recent and old clots. In all the author's cases in which the placenta was detached over an area of a hand's breadth the infants died. With regard to the pathology of this condition, the author regards it as a sequel to a general poisoning, which in one case gives rise to eclampsia, in another to early detachment of the placenta, and in yet another to both these manifestations.

157. Cancer of the Cervix after Subtotal Hysterectomy.

R. MONOD (*La Gynécologie*, October, 1926, p. 614) states that the frequence of development of carcinoma in the cervical stump after subtotal hysterectomy is considerably greater than has been supposed. In addition to 40 cases reported in 1910 he has been able to trace 101 new ones. Many patients, he finds, are treated by radiotherapy without having been to gynaecological clinics. About one-third of the cases occur within so short a time of the removal of the major part of the uterus that it is probable that the carcinoma had originally an endocervical site and was present in an early stage at the time of operation. Probably in such cases, metrorrhagia occurring about the age of 40 has been erroneously attributed to myoma or chronic metritis. He adds that in the interpretation of biopsy findings, it must be remembered that the infiltrating forms of endocervical carcinoma usually give negative reports after curetting, and that it is advisable to obtain thorough dilatation by means of laminaria tents and to excise widely in the suspected area. For cancer occurring later in the cervical stump radium therapy is the treatment of choice. The prognosis, however, is not good; among 17 cases Oppert had no survival after eighteen months. Out of 14 cases treated by Vallon there were 3 survivals only of two to three years; and of 17 cases treated at the Paris Radium Institute 6 appeared to be cured at the end of intervals of two to five years.

158. Occipito-posterior Presentation.

MERCKEN (*Gynécol. et Obstét.*, 1926, xiv, 5, p. 343) remarks that occipito-posterior presentations of the vertex may turn during the course of labour so that the occiput goes towards the pubis or the sacrum; corresponding to these there are two modes of forceps application, whereby it is sought to turn the occiput respectively forwards or backwards. At the Lausanne Maternity Hospital it is the rule in forceps cases to bring about delivery with the occiput posterior, the greater fontanelle being turned forwards. Analysing 100 cases of occipito-posterior positions treated during four years and constituting 3 per cent. of vertex presentations, Mercken states that in 57 the occiput turned forward spontaneously and in 43 backward. The left occipito-posterior positions showed a much greater tendency than the right to persist in the posterior position. Pelvic contraction did not appear to favour occurrence of posterior positions. It is admitted that the perineum is more liable to suffer by delivery of the posterior than the anterior occiput; in correspondence with the posterior position there was a larger proportion of tears of the first degree and of episiotomies. In the occipito-posterior cases labour lasted more than thirty-two hours in 14 per cent. of cases as compared with 5 per cent. of occipito-anterior cases. In the series of 100 cases there were no stillbirths; this, together with the fact that 90 per cent. of persistent occipito-posterior presentations terminated by spontaneous delivery, is taken to justify the treatment at this clinic.

159. Urethral Stricture in Women.

W. S. PUGH (*Journ. Amer. Med. Assoc.*, November 27th, 1926, p. 1790), in view of the relief to urinary symptoms which frequently follows cystoscopy in women, concludes that urethral stricture is a definite pathological entity of more common occurrence than is generally supposed. He believes that the association of a urethral infection with a gonorrhoeal vaginitis is often overlooked, and that the stricture is almost always the result of an antecedent urethritis which has become chronic. The stricture formation usually commences on the floor of the urethra, and in many cases is annular with a pathology similar to the corresponding condition in the male. The lesion may involve the entire canal, but the anterior portion, especially at the meatus, is most frequently affected. Dysuria, urgency, and frequency are among the most important symptoms, and signs of toxaemia may be present. In some cases the symptoms are referable to the upper urinary tract, showing the relation between the urethra and kidneys through the sympathetic system. The diagnosis may always be established by using the bulbous bougie, and urethroscopy is indicated in urinary lesions in the female. Prognosis appears to depend largely upon the etiological factor, soft infiltrations responding well to treatment, while the prognosis for dense strictures is doubtful. Pugh advocates treatment by gentle dilatation, deprecating any form of rapid dilatation; operative procedures should only be employed in filiform types or complete obstruction. Commencing with the largest bougie that will pass the stricture, an increase of two numbers a week up to No. 26, or a little larger, should be made, followed by the passage once a month for a year of a large dilator.

160. Relation of Diseases of the Pelvic Alimentary and Genital Viscera.

E. VOGT (*Med. Klinik*, December 24th, 1926, p. 1986) discusses the relations of carcinoma of the rectum and of the sigmoid with the internal genitalia in women. Rectal cancer may manifest itself first during pregnancy, and whenever there is any bleeding from the bowel haemorrhoids should not be diagnosed until after a rectal examination. In rectal carcinoma occurring during pregnancy Vogt advises Caesarean section if the child is viable, followed by an operation on the rectum. He states that it is now known that in cancer of the internal genitalia, of the breast, or of the rectum occurring during pregnancy, the prognosis is rendered distinctly more favourable by changes in the internal secretions, and the increased activity of all vital processes. In making a diagnosis *of left ovarian or tubal disease the possibility of cancer of the* sigmoid must be borne in mind. Such a tumour may be so large and mobile as to suggest an adnexal tumour until examination under an anaesthetic renders the diagnosis clear. Carcinoma of the sigmoid may produce symptoms of simple stricture for a long period before its malignancy is discovered; 20 per cent. of ovarian carcinomata, with or without ascites, are of metastatic origin. The primary growth, in the great majority of instances, is in the alimentary canal, the most frequent sites after this being the gall bladder, uterus, or breast. Whenever bilateral ovarian carcinoma is found the alimentary canal should be explored and any tumour, however small, should be removed. In the last stage of cancer of the cervix the growth may invade the rectum, thus producing constipation and possibly obstruction; recto-vaginal fistula may occur also. Cancer in the body of a retroflexed senile uterus may invade the rectum. Dermoids, although not malignant, may drag down the mesosigmoid and so reach the intestinal wall. Discharge of pus from the rectum is usually due to a ruptured pyosalpinx, especially when of tuberculous origin. Puerperal parametritis may produce an abscess in the pouch of Douglas; this may rupture into the rectum or vagina. An abscess due to gonorrhoeal pelvic peritonitis usually clears up when the pus has reached the bowel. An unsuitable pessary may produce recto-vaginal fistula; Vogt strongly condemns wing and stem pessaries.

Pathology.

161. Clear Cerebro-spinal fluid in Epidemic Cerebro-spinal Meningitis.

ACCORDING to DUCAMP (*Progrès méd.*, November 27th, 1926, p. 1781) clear cerebro-spinal fluid may be found sometimes in the course of epidemic cerebro-spinal meningitis. In advanced cases when the fluid is purulent or turbid at the height of the disease it may have been clear either at the onset—that is, within the first forty-eight hours—or become clear during the period of subsidence, where polymorphonucleosis is being replaced by lymphocytosis. The cerebro-spinal fluid may remain clear throughout the disease in three conditions—namely, (1) incomplete attenuated cases; (2) normal cases with persistent lymphocytosis, or with a microscopically and macroscopically normal fluid; in such cases the lateral ventricles have been found to contain turbid fluid; and (3) fulminating cases, of which Ducamp records an example in which meningococcal meningitis gave rise to a lymphocytosis only. The practical conclusion drawn from a study of such cases is that an intrathecal injection of polyvalent anti-meningococcic serum is usually the best treatment for a case of acute meningitis during an epidemic of cerebro-spinal fever.

162. Conditions of Anaerobic Growth.

JUDA H. QUASTEL and MARJORY STEPHENSON (*Biochem. Journ.*, xx, No. 5, 1926, p. 1125) have advanced a hypothesis to explain why strictly anaerobic bacteria are unable to flourish in the presence of free oxygen. Working with *B. sporogenes* they showed that *if tryptic broth is inoculated with this organism* there is no growth within eighteen hours, but that if 0.1 per cent. of cystein is added to the medium a heavy growth occurs in this time, even when incubation is carried out aerobically. The cystein therefore acts either by its preventing the access of oxygen to the cell or by its ability to reduce intracellular peroxide. They then showed that if a stream of oxygen is bubbled through a suspension of *B. sporogenes*, which is then transferred to broth, growth occurs in eighteen hours if the broth contains cystein, but not for sixty-six hours if no cystein has been added. Clearly the oxygen has not killed the organisms; but it has decreased their ability to reproduce in a plain broth medium. The long lag phase is completely abolished by the presence of cystein in the broth. This lag phase was not due to the presence of peroxides in the cell, because in oxygenated suspensions in which the peroxide was reduced by cystein—which was itself subsequently removed—the same delay growth occurred. Since neither oxygen nor peroxides actua kill the organisms, and since growth occurs without p liminary lag in a cystein medium, it would appear that t long latent phase in plain tryptic broth is occupied by t production of hydrosulphides which enable the organisms proliferate. The authors suggest that before growth *B. sporogenes* can occur reducing substances, if not alrea present in the medium, must be formed in such quantity *to attain a certain critical reduction potential. The effect* oxygen in preventing growth is due to its removal of su stances responsible for the maintenance of this critic potential. Under aerobic conditions the reducing substanc can never be formed in sufficient quantity—in plain broth to neutralize their removal by the free oxygen present. B if reducing substances, such as cystein, are added to t medium, the critical reduction potential is obtained, and t organisms can therefore start growing immediately, ev under aerobic conditions.

163. The Diagnostic Significance of Urinary Diastase.

L. KREYBERG (*Norsk Mag. f. Laegevid.*, November, 19 p. 992) set out to determine the following questions: (1) t normal diastase content of the urine; (2) the significance the increased diastase content; (3) the diastase content the urine in the course of diseases of the pancreas a salivary glands. The technique corresponded to Wohlg muth's short test. Urine in decreasing amounts (1/2 c.cm *1/4 c.cm., 1/8 c.cm., etc.*) was mixed in a set of test tub with 0.9 per cent. saline solution so as to make a total volu of 1 c.cm.; 2 c.cm. of 1 in 1,000 watery solution of starch w added to each tube. After the tubes had been incubated f half an hour at 38° C. the diastatic action was increased b the addition of iodine, and the diastatic index showed ho many cubic centimetres of the starch solution were tran formed by 1 c.cm. of the urine tested. Among 235 health persons examined the index ranged from 4 to 64. Acu diseases of the pancreas and salivary glands usually, if n always, were accompanied by a considerable rise of th index. The rise was sudden and very often of short duratio Several acute febrile and abdominal diseases were accom panied by a moderate rise of the index, probably as th result of slight damage to the pancreas.

164. Circulation of the Cerebro-spinal Fluid.

CATHELIN (*Rev. Scientif.*, November 27th, 1926, p. 679) believe that there are no to-and-fro movements of the cerebro-spin fluid and that the subarachnoid mucous membrane is n permeable; it is a barrier rather than a filter, and the fluid neither its product nor a filtrate. There exists a glandul apparatus for the secretion of the liquid, which, coming fro the blood of the choroid plexus, returns to the blood by th perivascular sheaths or lymphatics. Cathelin asserts tha there is a definite circulation of the spinal fluid, as in th case of the blood and lymphatic systems. He believes the the change in composition of the circulating cerebro-spin and lymph fluids occurs in the spongy tissue of the per vascular sheaths. He found that subarachnoid injections Prussian blue, passing through the perineural sheath and th [illegible] reached the lymphatic ganglia, and coloured th vessels of the cistern of Pecquet, th reat lymphatic vessel. Methylene blu injected into the subarachnoid space, stained in certain case limited segments of the immediate marrow, and in the grea majority of cases coloured the marrow and the isthmus an base of the brain, penetrating into the ventricles. Th presence of the colouring matter in the cranial sinuses, th jugular veins, and the cranial venous plexuses indicates direct communication between the subarachnoid space an the venous system. Cathelin thinks that this knowledge o the true circulation of the cerebro-spinal fluid is of grea importance in medico-surgical procedures.

165. The Complement Fixation Test in Gonorrhoea.

I. GHEORGHIU (C. R. Soc. de Biologie, December 31st, 1926 p. 1577) has performed 400 complement fixation tests o patients with gonorrhoea. The antigen used was a salin suspension of an eighteen-hour culture of the gonococcus several strains of the organism being used; the suspensio was heated to 50° C. for thirty minutes. Of 41 cases o urethritis lasting six days or less 35 reacted positively. O 283 cases of urethritis lasting from *twenty to thirty days* al reacted positively. All cases of gonorrheal complications such as arthritis, salpingo-oöphoritis, and endocarditis were positive; the only exception was a case of kerato conjunctivitis. Control serums from patients with rheum atism, gout, arthritis, and endocarditis of non-gonorrhoea origin were uniformly negative, and all gonorrhoeal patient who had been cured gave a negative reaction. The author in summarizing his results, states that all patients in whon the gonococcus was demonstrated reacted positively.

EPITOME OF CURRENT MEDICAL LITERATURE.

Medicine.

166. Veronal Poisoning.

M. AJAZZI-MANCINI (*Il Policlinico*, Sez. Med., November 1st, 1926, p. 614) reports a case of fatal veronal poisoning in a woman, aged 43, who died after two days of broncho-pneumonia. At the necropsy the author found 0.683 gram of veronal in the brain and 0.182 gram in the liver. The preponderance of the drug in the brain agrees with other records. Bronchopneumonia as a final phase is common in veronal poisoning, and the author believes it to be due to the depressive effect of the drug on the neurotrophic system, rendering the pneumonic tissue much more susceptible to bacteria. Experiments on animals have confirmed this view. As regards elimination, the drug may be found in the urine for the first four or five days, but usually has disappeared before ten days have elapsed. Apart from the history, veronal poisoning has to be distinguished from cerebral haemorrhage, morphine poisoning, alcoholism, encephalitis, [illegible] traemia, diabetic [illegible] he chief reliance [illegible] h as strychnine, [illegible]

167. Early Syphilitic Aortitis.

H.-W. GRAF (*Rev. Méd. de la Suisse Romande*, November 25th, 1926, p. 855) finds that aortitis, the most frequent and tardiest manifestation of syphilis, occurs in 70 per cent. of cases. This affection usually appears between the ages of 45 and 50, on an average about twenty years after infection. V. Romberg, who studied 278 cases, places the lowest interval at four years and the maximum at forty-three. It is impossible to judge when these [illegible] ons (usually in the supracoronary [illegible] aorta) really commence, as they [illegible] their presence by subjective or ob[illegible] necropsies performed by Stadler on twelve syphilitic patients dying before the age of 30 no macroscopic alteration of the aorta was found. Bruhns and Wiesner found that in necropsies on the newborn evidences of congenital syphilitic aortitis, consisting of an infiltration of the media and adventitia of mononuclear cells or epithelioids, but no true gummata, were seen. Graf states that under the latest methods of treatment there has been a modification in the general evolution of syphilis, and Willmanns has shown that the tertiary cutaneous and osseous symptoms are giving place to nervous and visceral manifestations, the change being attributed to salvarsan. Jungmann and Halis have shown from necropsies that the number of cases with specific aortic lesions from 1921 to 1925 has nearly trebled those from 1904 to 1908, and that the interval of symptomatic appearance is much shorter in the treated than in the untreated. Gürich found *post mortem* these specific lesions in fifty cases in 1912 as against ten cases in 1909. These results lead the present author to conclude that systematic medication by the arseno-benzols is an important determining factor in the increase in frequency and early existence of specific aortic lesions, but that, nevertheless, the benefits from salvarsan are so great, and complete cure so often obtained, that this treatment should not be abandoned. He insists upon the importance of systematic and repeated examinations of the heart in all cases of syphilis, even in the absence of every subjective symptom. V. Romberg has shown that accentuation of the second aortic sound with a normal or lowered arterial pressure is the earliest objective symptom of supracoronary aortitis; that it can exist in the absence of a systolic murmur at the orifice; and that it is wise to combine methods of clinical exploration and of radiography in order to detect aortic changes at their commencement.

168. Gastric Crises in Tabes.

J. WAGNER-JAUREGG (*Wien. klin. Woch.*, September 16th, 1926, p. 1093) remarks that gastric crises are frequently observed in cases of tabes which are in a stationary condition and show a negative Wassermann reaction in the blood and cerebro-spinal fluid, so that the syphilitic process appears to have subsided. The dearth of tabetic symptoms in cases of gastric crises has been described by many observers. In some cases a gastric crisis is the first indication of the disease, and in rare instances may be the only symptom. Very little is known about the histological changes in the afferent nerves of the stomach in gastric crises, and the relation of these crises to the dorsal segment of the spinal cord is based more on clinical experience than on anatomical investigations. The unsatisfactory action of opium and its derivatives on the lightning pains of tabes is also illustrated in gastric crises, but with this difference—that in the former condition pain is the only symptom requiring treatment and therefore may yield to various antineuralgic drugs, whereas in gastric crises there is also the nutritional disturbance. Antisyphilitic treatment often proves ineffective. Förster at first obtained very good results by section of the posterior roots of the seventh to the tenth dorsal nerves, which supply the stomach with sensation. Subsequent failures induced him to divide more roots—namely, the fifth to the twelfth, and even the first two lumbar nerves. All operative methods, however, are liable to failure or recurrence of symptoms. Survival in any case does not last many months. In not a few cases malarial therapy has produced good results, although recurrences have also been observed after this. It has, however, the advantage over operative procedure that it can be repeated several times and may be successful when operation fails.

169. Hemiplegia in Epidemic Encephalitis.

H. VERGER (*Gaz. hebd. des Sci. Med. de Bordeaux*, November 27th, 1926, p. 710) remarks that though hemiplegia is generally regarded as not being one of the sequels of epidemic encephalitis, during the last three years at least four examples of the kind have been reported. He now reports two cases in women, one aged 29 and the other 44, who suddenly developed right and left hemiplegia respectively. Syphilis was excluded in both cases by a negative Wassermann reaction and the failure of specific treatment, while the existence of epidemic encephalitis was suggested by the presence of stupor, myoclonus, somnolence, and slight fever.

Surgery.

170. Ischio-Pubic Osteochondritis.

M. WÜLFING (*Deut. Zeit. f. Chir.*, December, 1926, p. 413) remarks that a very large number of articles have been published on osteochondritis, although it is only fifteen years since it was first described as an independent disease. Most of these articles, however, refer to that form of osteochondritis known as osteitis deformans juvenilis coxae, or the Calvé-Legg-Perthes disease. Next in frequency comes apophysitis tibiae, or Schlatter-Osgood's disease, Köhler's disease of the os naviculare pedis, and various other rare forms. Examples of osteochondritic changes in the pelvis, of which van Neck was the first to report two cases, are extremely uncommon. Wülfing, who records two cases, in a boy aged 12 and a girl aged 9 respectively, maintains that in the case of indefinite disturbance of gait suggesting disease of the hip-joint, the possibility of ischio-pubic osteochondritis should be considered if hip-joint disease can be excluded, as the symptoms are the same in both conditions. The defective ossification is manifested in the skiagram by a globular thickening at the junction of the pubis and ischium. The symptoms rapidly subside under conservative treatment and rest in bed. It is doubtful if the administration of calcium preparations, *x*-ray treatment, or artificial sunlight hastens recovery.

171. Diseases of the Gall Bladder.

E. A. GRAHAM (*Amer. Journ. Med. Sci.*, November, 1926, p. 625) believes that in man hepatitis is a constant accompaniment of cholecystitis, that perhaps in a majority of cases cholecystitis is produced by a direct extension of inflammation from a liver already inflamed to the wall of the gall bladder, and that this extension of inflammation occurs through the abundant lymphatic anastomosis between the liver and the gall bladder, the spread in the gall bladder being from the serous to the mucous surface, as the richest supply of lymphatic vessels in the gall bladder is situated immediately beneath the serosa. This conception of the pathogenesis of cholecystitis might also explain the frequency of vomiting as an early symptom, since peritoneal irritation would almost certainly occur early from the proximity of the lymphatic vessels to the peritoneal coat of the gall bladder. Hepatitis may follow experimentally produced cholecystitis, so that the establishment of a vicious circle between the liver and the gall bladder is suggested. Some cases of cholecystitis are due to haematogenous infections of the gall bladder, and others are contact infections with primary involvement of the mucosa. Kodama thinks that there is an intimate

relation between the lymphatics of the first part of the duodenum and those of the gall bladder. This would indicate that a duodenal ulcer might induce cholecystitis directly by means of lymphatic extension without the intervention of hepatitis. For the diagnosis of cholecystitis Graham recommends radiography, and describes his technique for the administration of sodium phenoltetraiodophthalein. He claims for this method that this, being a functional test of the gall bladder, discloses abnormality in very early and mild cases of cholecystitis, perhaps even before structural pathological changes are visible. Graham reports also that cholecystographic studies show that bile from the gall bladder does pass out through the cystic duct. He rather doubts the existence of the sphincter of Oddi, and describes experiments to show that it is of little importance in any case. Recent experiments by Copher and Kodama have shown that the emptying of the gall bladder is purely passive and can be explained on simple mechanical principles. Graham found that an artificial elastic gall bladder acted like a normal gall bladder in emptying and filling. Cholecystography showed that it behaved like a normal gall bladder, except for the inability to concentrate the bile by absorption of water.

172. Carcinoma of the Small Intestine.

E. D. CLARK (*Surg., Gynecol., and Obstet.*, December, 1926, p. 757) reports a case of colloid carcinoma of the small intestine. Commenting on the unusual occurrence of any type of carcinoma in this situation the author states that the growth appears more frequently at the upper and lower ends than in the middle of the small intestine. The symptoms are those of intestinal obstruction, and in no case has the diagnosis been made before operation. Clark advises that examination of the stools should be made for occult blood when there are indefinite symptoms suggesting partial intestinal obstruction. He adds that *x* rays give valuable assistance in diagnosing intestinal stenosis and in locating the lesion. Clark's patient was a woman, aged 59, whose first symptoms were severe epigastric pain, intestinal colic, and vomiting attacks occurring one to three hours after meals at intervals of two or three days. Constipation was present, but lavage and enemata gave marked relief. An *x*-ray examination showed marked distension of the small intestine, but no operation was permitted until complete obstruction supervened. The tumour mass was found in the ileum, about twelve inches from the ileo-caecal valve; no enlarged glands were detected. Recovery was uneventful.

173. Drainage after Cholecystectomy.

O. H. WANGENSTEEN (*Annals of Surgery*, December, 1926, p. 821) remarks that the advocates of dispensing with drainage after cholecystectomy have in mind three advantages which accompany its omission: diminution of adhesions, more rapid healing, and less danger of hernia. The chief deterrent has been the danger to life through the escape of bile, haemorrhage, and infection. This "ideal cholecystectomy" is not considered by the author to be a safe procedure. Numerous instances are reported where a second laparotomy was necessary because of bile leakage when drainage was omitted. A still greater number of patients died because of the escape of bile and the failure to drain. The leakage of bile may be early or delayed. That occurring soon after removal of the gall bladder is due to injury to the liver bed or severance of small aberrant bile ducts. The delayed escape of bile is occasioned by insufficiency of the cystic duct occlusion. In view of the risks of its omission drainage is therefore considered necessary. A gutta-percha tissue drain down to the stump of the cystic duct is said to be adequate. The drain should be left in undisturbed for about eight days and then removed gradually.

174. Malignant Tumours of the Long Bones.

W. B. COLEY and B. L. COLEY (*Arch. Surg.*, December, 1926, p. 779) dispute the current view that periosteal sarcoma of the long bones is one of the most malignant of all tumours, and that prognosis in these cases is hopeless. They consider that prognosis depends on early diagnosis and careful judgement in the selection of treatment. Amputation alone, even if early, gives little hope of cure. Radium and *x* rays, even when pushed, have failed to effect a permanent cure. The mixed toxins of erysipelas and *Bacillus prodigiosus* alone have effected a cure in a certain number of cases of the round- or spindle-cell type characterized by little production of bone. The mixed toxins and radium combined have given even better results, but no benefit has been obtained in cases associated with new bone production. The authors believe that the choice of treatment depends on this condition, and as a start the injection of toxins and the local application of radium may be tried. If marked improvement is noted the treatment may be continued, but, otherwise, amputation should be performed. Ten patients with inoperable disease treated with toxins and radium have remained alive and well for five to twenty-four years subsequently. This, the authors add, should prevent hope being abandoned in cases beyond surgical relief.

Therapeutics.

175. Vaccine Treatment of Whooping-cough.

D. VAN DER KOOI (*Nederl. Tijdschr. v. Geneesk.*, November 27th, 1926, p. 2455) refers to previous articles by Dutch writers on the subject (see *Epitome*, 1926, vol. i. paras. 40, 343, and 344) and records his observations on twenty-five cases which he treated with a polyvalent pertussis vaccine in successive doses of 1,000, 2,000, 3,000, and 5,000 million pertussis bacilli, with intervals of three, three, and four days between each injection. The results were classified in the following groups: (1) Two cases with complete recovery on the sixth day, when the third injection was given. (2) Fourteen cases which showed considerable improvement on the tenth day, when the third injection was given, and were practically cured on the seventeenth day, a week after the last injection. (3) Seven cases showed very little improvement on the tenth day, when the fourth injection was given, but were considerably improved by the seventeenth day. (4) Two cases which were not affected by the treatment. Thus in sixteen of the twenty-five cases an excellent result was obtained. The author's conclusions are as follows. Polyvalent whooping-cough vaccine is very beneficial in uncomplicated whooping-cough; in cases complicated by even mild attacks of bronchitis a mixed vaccine consisting of Bordet-Gengou bacilli, influenza bacilli, and pneumococci is best. When general or focal reactions occur caution is necessary in increasing the dose. General or focal reactions do not justify a favourable prognosis. In order to prevent local reactions the injections are best given in the trunk—for example, between the scapulae. Careful attention must be paid to unsuccessful cases, as thereby suggestions may be found for improving the method.

176. L. H. VAN DER VELDE (ibid., December 11th, 1926, p. 2665) reports his observations on seventy-three cases of whooping-cough in children treated with polyvalent vaccine from the Dutch Serological Institute at Utrecht. In sixty-one, or 80 per cent., there was rapid improvement, but of the remaining twelve none derived any direct benefit from the treatment, and four, who already had bronchopneumonia, died. The vaccine is most effective when it is injected in the catarrhal stage or as early as possible after the first typical paroxysm. At first four injections were given in doses of 1,000, 2,000, 3,000, and 4,000 million bacteria above the age of 2 years, and below that age 500, 1,000, 2,000, and 3,000 million. In protracted cases three more injections were given of 5,000, 6,000, and 7,000 million. Lately the doses have been 2,500, 5,000, and 7,000 million irrespective of age, only three injections being given, and always intracutaneously.

177. Mercurochrome in Local and General Infections.

H. H. YOUNG (*Journ. Amer. Med. Assoc.*, October 23rd, 1926, p. 1366), in a study of 680 cases comprising septicaemias, general infections, and local infections, reports that 74.4 per cent. showed great improvement or cure after intravenous injections of mercurochrome, and 19.6 per cent. complete failures. In the series were 13 cases of pernicious anaemia, in 10 of which the treatment was followed by immediate improvement, thus strongly supporting the belief that this disease is the result of a deep-seated, chronic infection. He states that in two-thirds of the cases there was little, if any, reaction; marked elevation in temperature, accompanied by a chill and followed by a sudden drop, generally occurred, but was usually followed by obvious benefit and often complete cure. Young states that when full doses are used care should be exercised, and the intervals between injections should be at least three days. A pronounced rise in the blood cell count was found after the injections, due probably to stimulation of the blood-forming organs. The author believes that mercurochrome has so great an action in curing infectious conditions that curative intravenous therapy has now become an established procedure.

178. Potassium Borotartrate in Epilepsy.

W. G. LENNOX and L. H. WRIGHT (*Boston Med. and Surg. Journ.*, December 23rd, 1926, p. 1199) refer to the treatment of epilepsy by potassium borotartrate, as advocated by P. Marie, who reported success with ten epileptics. The therapeutic action of this salt may be due to its reduction of the alkalinity of the blood. The present authors selected eight epileptic patients who for six months had received no sedative drugs; for one month each patient received 15 grains

of potassium borotartrate thrice daily. In the following month no medicinal treatment was given. In the third month each patient received 1½ grains of luminal twice daily. In the fourth month no drugs were given, and in the last month both luminal and borotartrate were given in the previous doses. The charts showed that during each month of treatment the epileptic attacks were somewhat less frequent than during subsequent drugless months, but that the only distinct fall in the number of convulsions occurred in the month in which luminal was given when major attacks were reduced to less than half their usual frequency. There was no corresponding decrease in the number of minor attacks. Patients who suffered from petit mal did not seem to do so well on a combination of the borotartrate and luminal as on luminal alone. In the case of a woman who had very frequent attacks potassium borotartrate reduced the daily attacks to less than ten, while luminal arrested them completely. When either drug was stopped, the number of attacks increased greatly. The authors conclude, therefore, that potassium borotartrate, though useful, is less effective than luminal.

179. Treatment of Erysipelas.

E. S. PLATOU and L. RIGLER (*Arch. Intern. Med.*, November 15th, 1926, p. 573), comparing the reports of eighteen unselected cases of erysipelas treated by iced magnesium sulphate and glycerin packs with a group of twenty-three cases treated by *x* rays, found vastly superior results from the latter method. Among those treated by the routine procedure there were four deaths, while among the twenty-three cases treated by *x* rays there was only one death, that of a child recovering from measles; the local signs of erysipelas in this child disappeared within thirty hours, but the toxic signs persisted, death being due to bronchopneumonia. In the majority of cases the temperature dropped to normal within twenty-four hours, and pain, toxicity, and general malaise disappeared within one or two days, whereas in cases treated by local applications the symptoms lasted longer. While practically all the control cases showed spreading of the disease after treatment was begun, only one patient treated by *x* rays showed a very slight extension. The authors conclude that treatment by this method effectively shortens the course and decreases the morbidity and mortality of erysipelas, producing a rapid improvement in both its local and general manifestations.

Laryngology and Otology.

180. Auditory Complications of Neosalvarsan Treatment.

C. FERRETTI (*Arch. Ital. di Otol.*, November, 1926. p. 605), discussing the effects of neosalvarsan on the apparatus of hearing, states that following the administration of this substance to human beings there have been inflammations of the auditory nerves on one or both sides, with or without other cranial nerves being affected. Seven rabbits were given intravenous injections of varying strengths and of varying frequency, and in none was he able to detect any interference with the function of the auditory apparatus, though some showed marked somnolence and one or two of them stages of excitement. In one rabbit, to which 2.05 grams had been given in ten doses, there was some fragmentation of Nissl's granules in cells in the region of the ventral cochlear nucleus and of the tuberculum acusticum. Another animal given a large dose of 0.45 gram was killed five days later, and the chromatin material in the cells of the spiral ganglion of Corti was found not as granules but dispersed evenly throughout the protoplasm; the nucleus tended markedly to move to the periphery of the cell. In no animal was there any change in the myelin sheath, the axis cylinder of the acoustic nerve, or in the sensory epithelium of the organ of Corti.

181. Naso-pharyngeal Fibroma.

C. MORARD (*Rev. Méd. de la Suisse Romande*, December 25th, 1926, p. 934) records a case of fibroma of the naso-pharynx in a young man, aged 22, in whom a large tumour filled the naso-pharynx and prevented nasal respiration, but did not bleed. After an unsuccessful attempt at snaring the growth it was removed in two attempts by means of strong forceps. The condition recurred after a few months, and three years later Morard again removed the growth and placed the patient on testicular gland therapy, believing that these tumours have a definite connexion with the male genital glands. The author reports that they usually occur in youths who have arrived at sexual maturity. He has also found, and his observations are confirmed by Escat, that they always occur in young men who have been absolutely continent and who are usually of a hard-working and studious nature. It is rare to find such tumours in married men or in immature boys. He compares this tumour with the fibromyoma of the uterus which occurs more often in sterile women or those with few children than in multiparous women. The uterine tumour stops growing or shrinks when the ovaries cease to function. The naso-pharyngeal growth, on the contrary, becomes more active during incomplete testicular activity. In dealing with the post-operative haemorrhage the author has had to pack the post-nasal space, and remarks how rarely middle-ear disease occurs after such treatment, despite the foul smell of a tampon after having been *in situ* for twelve to twenty-four hours.

182. Allergy in Oto-laryngology.

W. W. DUKE (*Arch. of Otolaryngol.*, November, 1926, p. 430) reviews the recent literature on allergy, mentioning particularly the transfer of hypersensitiveness and desensitization. Local sensitization has been repeatedly produced in the skin of animals and man, and the local areas can be again desensitized by the injection of the appropriate solutions. The theory of Zinsser that in human hypersensitiveness the immune bodies are attached to the tissues and in animals are free in the circulating fluids has been confirmed by experimental work with hay-fever serum. In some cases where there has been transfusion of blood to a sensitized patient there has resulted a very severe and serious reaction. Transfusion of blood from a sensitized donor to a normal individual does not appear to carry the sensitization with it. It has been suggested that most of the sensitizing bodies are foreign proteins, but that in some cases a new protein is formed *in vivo* by the action of some outside factor such as heat or light. As regards treatment, a number of cases of radical cervical sympathectomy have been reported; unilaterally it has proved ineffective, but the bilateral operation appears to offer some chance of alleviation. Some good results have been obtained by exhibition of calcium iodide, and improvement is reported after the use of iodized oils. In pollen therapy better results are obtained by giving the treatment during the season than by prophylactic doses. It is shown that after treatment in one season there will be no diminution in sensitiveness the following season, but that the patient will respond equally well to the treatment each year. Duke does not consider that surgical treatment of nasal lesions will of itself cure any cases of hay fever or asthma, but agrees that gross abnormalities must be corrected before success can be obtained by other methods.

183. Diagnosis of Accessory Nasal Sinus Disease.

A. A. HAYDEN (*Journ. Amer. Med. Assoc.*, October 23rd, 1926, p. 1390) finds that auscultation and percussion are valuable procedures in the diagnosis of accessory nasal sinus disease. Sound waves travel more easily through denser mediums, and the denser sinus will naturally transmit sound more readily. The density may be increased by thickening of the mucosal lining, the result of recent congestion or old and recurrent inflammations, by fluid or new growths, and by a combination of any or all of these factors. Other things being equal and both sinuses normal, the smaller should transmit sound better than the larger, as the impulses travel less distance through a less dense medium (the air of the sinus) and farther through a denser medium (bone, muscle, skin). Conversely, a large sinus with thickened walls, especially when filled with fluid, neoplasms, or both, affords a much better path for sound transmission than the normal sinus of corresponding size. The differential stethoscope is essential for all sinus auscultation, because opposite sinuses should be auscultated as nearly simultaneously as possible, and the following sounds may be utilized: Conversation, breathing, humming, tuning-fork vibration for relative intensity, and tuning-fork vibration for duration. Percussion—a blow on the top of the head—is felt more distinctly in the acutely or subacutely diseased sinuses. Hayden describes cases in which by the use of these methods he has been enabled to make correct diagnoses of sinus disease.

Obstetrics and Gynaecology.

184. Mitral Stenosis in Pregnancy.

ED. DOUMER (*Arch. des Mal. du Cœur des Vaisseaux et du Sang*, December, 1926, p. 791) observes that while acute pulmonary oedema is particularly ominous in cases of aortic disease, of hypertension, and in Bright's disease, it is also one of the complications that may occur in pregnant women with mitral stenosis. Apart from pregnancy it is said that the occurrence of pulmonary oedema in the course of mitral stenosis is quite exceptional. He reports three cases of minor attacks of pulmonary oedema, and concludes that they are much more common than has been believed hitherto. Doumer's patients appeared to have advanced stenosis with but a moderate auricular dilatation. These cases tend to

disprove the classic theory that hypertension is the dominant factor in the etiology of pulmonary oedema; even in the case of mitral stenosis it may occur without stasis or pulmonary hypertension. Pulmonary oedema due to mitral stenosis, apart from pregnancy, often follows a second infection, particularly a recurrence of articular rheumatism, as several previous writers have observed. No such factor occurred in the cases now reported. Donner draws attention to the remarkable fact that although pregnancy in a case of mitral stenosis is considered to be an important factor in the production of acute pulmonary oedema in one of his patients the symptoms disappeared during pregnancy. In explanation of this he states that pregnancy may produce cardiac dilatation and frequently causes the breakdown of a hitherto well compensated mitral lesion; by producing auricular dilatation it frequently evokes a reflex oedema, but when the auricle is already dilated pregnancy completes the dilatation, and may thus cause pre-existing crises of oedema to disappear. Thus it is unnecessary to hold pregnancy responsible for any disturbance that may directly induce pulmonary oedema in order to explain the crises of oedema that are due to certain mitral lesions. Pregnancy is only a factor in cardiac dilatation, and Doumer's patient appears to show clearly that its consequences vary with the previous condition of the myocardium.

185. Estimation of Foetal Maturity.

R. JARDIN (*Gynécol. et Obstét.*, 1926, xiv, 4, p. 240) states that Béclard's discovery, made in 1819, that ossification commences before the end of foetal life in the lower epiphysis of the femur was forgotten for many years until its importance was emphasized by Orfila in 1825 and Casper in 1862. From radiological studies of the epiphyses above and below the knee-joint in premature and full-time babies Jardin has found that the centre of ossification for the lower epiphysis of the femur (Béclard's point) appears at the beginning of the ninth month of foetal life and is always present at term: the centre for the upper epiphysis of the tibia appears at eight and a half months, but is not always present at term. It is justifiable to conclude (1) that a new-born child weighing 5½ lb. or more and measuring 18 inches in length, having centres of ossification both in the lower end of the femur and the upper end of the tibia, is a full-time baby; (2) a child weighing more than 5½ lb. and measuring more than 18½ inches, and showing Béclard's point, is a full-time baby; (3) an infant of weight less than 5½ lb. and length of from 16½ to 17½ inches, possessing an early centre of ossification in the lower femoral epiphysis, is at the beginning of the ninth month; (4) a child showing no centre of ossification either in the lower end of the femur or the upper end of the tibia, and having a weight less than 4½ lb. and a length less than 16½ inches, has not reached the beginning of the ninth month of gestation.

186. Application of Leeches in Puerperal Phlebitis.

GONNET, JEANNIN, and JOSSERAND (*Lyon Médical*, December 5th, 1926, p. 657) observe that the occurrence of puerperal venous thrombosis is always serious on account of the possible complications and the prolonged rest that is necessary. They describe six cases in which they attempted to prevent thrombosis and to modify the coagulability of the blood by the application of leeches. It is known that leeches produce, not only a local haemophilia, but also a diminution of the coagulability of the circulating blood. In the case of a primipara, aged 25, pain commenced in the right groin and calf on the ninth day after a normal delivery, the temperature being 101.5°. Five leeches were applied to the external surface of the right thigh; the pain was relieved, but the fever persisted. On the fourteenth day there was slight oedema over the right tibia, and five leeches were applied to the right leg; two days later all symptoms had disappeared. In a case of breech presentation in another primipara, aged 28, premature rupture of membranes was followed by a difficult extraction. On the fifteenth day pain began in the right leg, with muscular weakness and oedema of the ankle. The next day five leeches were applied, and the treatment was repeated on three days in succession. The oedema and pain disappeared, but the temperature rose to 103°. In spite of the repeated application of leeches the fever and oedema persisted though the temperature fell to normal. On the fiftieth day the patient had excessive oedema of both legs, which had not been influenced by recent applications of leeches. The authors consider that the antithrombotic action was clear. One of them had seen a multipara who had phlegmasia after each of her eight confinements; after the last of these leeches were applied twice and no sign of phlebitis was found. The only complication in the series of cases was one of anaphylactic urticaria. The authors cannot accept the suggestion that the secretion of the leeches, passing into the circulation, dissolves the fibrin of the clots already formed, but think that it modifies coagulation appreciably and rapidly.

Pathology.

187. The Metabolism of Oxalic Acid.

G. VIALE (*Rev. Swl-Amer. de Endocrin.*, November, 1926, p. 967), as the result of experiments on rabbits and dogs, has come to the following conclusions. (1) Injection of insulin does not cause any definite changes in the quantity of oxalic acid in the blood. (2) Injection of insulin into rabbits and dogs considerably lowers the elimination of oxalic acid by the kidneys; the same effect is observed in diabetic patients. (3) Injection of adrenaline considerably increases oxaluria. Periodic and daily injection of adrenaline always has a more intense effect on glycosuria. (4) Removal of the pancreas increases oxaluria. (5) In phloridzin diabetes no appreciable changes in the elimination of oxalic acid are observed. (6) It is therefore probable that the oxalic acid is derived from the metabolism of carbohydrates. The origin of oxalic acid is regulated by the internal secretion of the pancreas. (7) Injection of insulin is indicated in the treatment of oxaluria.

188. Tetanus Agglutinins and Antitoxin in Human Serums.

G. E. COLEMAN and K. F. MEYER (*Journ. Infect. Dis.*, October, 1926, p. 332) examined the blood serums of 104 persons in San Francisco for the presence of agglutinins and antitoxin to the tetanus bacillus, continuing the inquiry of Bauer and Meyer in California into the frequency of the tetanus bacillus in the faeces, in which they found that 24.6 per cent. of 117 persons examined were excreting the bacillus in their stools. Of the eight serological types of tetanus bacilli Types 1 and 3 were the most frequent, being present in 66.6 and 18 per cent. respectively of the positive cases. In the present work the patients' serums were agglutinated with washed antigens of each of the types, with the exception of the locally rare Type 6. Of the 104 serums 20 per cent. contained no agglutinins in dilutions of 1 in 10; 50.9 per cent. contained agglutinins in a dilution of 1 in 20; and 16.3 per cent. contained agglutinins in a dilution of 1 in 40 to 1 in 60. The authors paid no attention to titres of less than 1 in 40, considering that agglutinins in a dilution less than this were probably due to non-specific causes. Of the 17 serums containing agglutinins at 1 in 40 or higher, 11 acted on Type 5, 5 on Type 2, and 4 on Type 1, some serums being able to agglutinate more than one type of bacillus. The predominance of agglutinins to Types 2 and 5 was unexpected, since the commonest types found in the faeces were Types 1 and 3; this discrepancy may be due to a higher degree of agglutinability of Types 2 and 5. Tests for antitoxin were made on 44 serums, chiefly those containing agglutinins; in no case was sufficient antitoxin found to neutralize two minimal lethal doses of toxin for the mouse. These results are not in accord with those of Ten Broeck and Bauer, who demonstrated the presence of antitoxin in 37.5 per cent. of the inhabitants of Pekin (*Epitome*, June 5th, 1926, para. 579). It [illegible] tetanus bacillus does not remain long [illegible] tinal tract of persons in California to [illegible] whereas in China, where the sanitary conditions are poorer, the bacillus may be able to establish some degree of permanency.

189. Bacteria in the Muscles and Blood of Normal Animals.

A. F. REITH (*Journ. Bacteriol.*, November, 1926, p. 367) finds that living bacteria are frequently present in the blood and muscles. He examined 42 hams taken from apparently healthy pigs (altogether 216 samples were tested with the strictest aseptic precautions). Of these, 77 per cent. were found to contain organisms capable of yielding growth in artificial media; the percentage containing anaerobes was 57. He also removed portions of the gracilis muscle from anaesthetized hogs, rabbits, and guinea-pigs, and made blood cultures at the same time. From the muscle bacteria were isolated in all the hogs, 61 per cent. of the rabbits, and 89 per cent. of the guinea-pigs. From the blood they were isolated in all the hogs, 67 per cent. of rabbits, and 33 per cent. of guinea-pigs. The highest percentage of positive blood cultures was obtained in the 1 in 100 dilutions, probably because in the lower dilutions the bactericidal power of the blood was sufficient in many instances to prevent growth. Finally, a series of 20 hogs was examined at different times after feeding, in order to ascertain whether there is any truth in the belief that the number of organisms in the tissues varies with the state of digestion. From the blood of all the animals bacteria were isolated. A full determination of the identity of the different organisms isolated from the tissues of the animals was not made; 59 per cent. were staphylococci, 22 per cent. bipolar rods, 19 per cent. Gram-positive rods, 16 per cent. other cocci, and 6 per cent. Gram-negative rods. The low proportion of Gram-negative rods indicates that the organisms do not as a rule gain entrance from the intestinal tract.

EPITOME OF CURRENT MEDICAL LITERATURE.

Medicine.

215. Concurrent Varicella and Herpes Zoster.

E. C. WILLCOX and J. D. ROLLESTON (*Brit. Journ. Child. Dis.*, October–December, 1926, p. 270) report the case of a boy, aged 4, who first developed a characteristic eruption of herpes zoster of the left side of the chest and four days later a generalized eruption of varicella, the lesions of which were scattered over the trunk, face, and scalp, and were also present on the palate, base of the uvula, and buccal mucosa. The lesions were in various stages of development, some being papular, others vesicular, and others umbilicated from partial escape of their contents. On the trunk the vesicles were uniformly circular or ovoid, the better developed ones being surrounded by the pink areola commonly present in chicken-pox. Commenting on the case Rolleston points out that by far the most frequent association of herpes zoster and varicella is the occurrence of zoster in one individual, followed by the eruption of varicella in another, usually after an interval of fourteen days, corresponding with the incubation period of varicella. A much rarer association is the occurrence of varicella in one individual, followed by the appearance of zoster in another with whom he had been in contact, of which only ten examples were collected by A. Netter in 1920 and fifteen by H. Netter in 1921. Intermediate in frequency is the group of cases, of which the present one is an example, consisting in the concurrence of zoster and varicella; of this group H. Netter has collected twenty-one cases. While some writers regard the concurrence of varicella and herpes zoster as due to dissemination of a virus which in the first instance attacks certain posterior roots only, Rolleston adopts the more obvious explanation that, in view of the extraordinary frequency of varicella and the rarity of zoster, there is nothing remarkable in the occasional association of the two diseases, though the association is a mere coincidence.

216. Voluntary Pulse Control.

A. S. HYMAN (*Amer. Heart Journ.*, December, 1926, p. 188) remarks that voluntary and conscious control of the radial pulse is rare though not unknown. Some individuals with loose joints can rotate the humerus until the brachial artery is wound round the bone and compressed thereby. More obscure cases are those in which the radial pulse is controlled by voluntary muscular contraction in persons who have unusual neuro-muscular reflexes. The author reports three cases. The first, a German soldier who had become a professional entertainer, claimed to be able to stop his heart at will. After making several "passes" the radial pulse would stop entirely for fifteen or twenty seconds, and then return gradually. Medical examination showed that while the radial pulse was impalpable the apical heart sounds were normal. Moreover, there was no change in the opposite radial pulse nor in either femoral artery. Apparently the man could compress his subclavian artery, but this could not be determined as he refused further examination. The second case, a man aged 51, had noticed that he was able "to will" his left radial pulse to become smaller, and once he stopped it for about fifteen seconds without appreciable effort. This arrest was not associated with any change in cardiac rhythm, nor with the pulsation of any other artery. Electro-cardiograms showed very small beats coming through the radial artery, although they were too small to be palpated. The block appeared to be in the left subclavian, where it crossed the first rib beneath the insertion of the scalenus anticus. There was no visible muscular contraction, but the fluorescent screen showed slight movement in the soft tissues beneath the outer end of the clavicle. The patient is not aware of muscle movement, but he soon experiences muscle fatigue, definitely localized in the deep neck muscles. The longest period during which the patient could stop the radial pulse was 18.6 seconds; at the end of an hour's experiment he lost this power for more than a few beats at a time. When standing no change was noted until the left arm was held horizontally at shoulder level, when the radial pulse returned. When the patient lay down the pulse could be controlled even when the arm was held vertically. The patient's general health was excellent. This appeared to be a clear case of so-called pulse control by unusual neuro-muscular development. The third patient, a neurotic girl aged 22, had had many attacks of tonsillitis in childhood and two attacks of acute rheumatism, which resulted in aortic and mitral disease. During a routine cardio-vascular examination it was observed that the left radial pulse was smaller than the right, but a few moments later the radial pulses were equal. Since childhood the patient had retained an unconscious fear whenever her pulse was taken; apparently it recalled the long period when she lay bedridden with rheumatic endocarditis. She admitted that the mere act of feeling her pulse was always associated with a strong desire to stop her heart entirely. Electro-cardiograms showed that, as in the two previous cases, there was no change in the cardiac cycle. Ability to control the pulse was lost rather quickly through fatigue. In this case also the site of the arterial obstruction was probably in the subclavian artery. The author adds that this type of pulse control must be clearly distinguished from that due to extreme vagotonia, in which the heart may be slowed even to 44 beats a minute when the breath is held, but the pulse, though slow, does not stop.

217. Purpura in Women.

W. DAVID (*Med. Klinik*, November 12th, 1926, p. 1755) describes five cases of an unusual purpuric condition in women: two were severe and ended fatally, in two recovery was slow, and one was still under treatment. The onset in all was sudden, with no history of previous attacks; the symptoms were invariably a haemorrhagic rash on the trunk and limbs, profuse bleeding from the gums, severe uterine haemorrhages, and blood in the urine and stools. The bones and joints were unaffected; there was no pain and no fever. One case showed actual multiple subcutaneous haematomata. The blood count in all cases showed a normal or decreased number of leucocytes; the erythrocytes were much diminished, ranging from 1,800,000 per c.mm. in a fatal case to 4,000,000 in the mildest. The haemoglobin count was 20 to 60 per cent.; in only one case was anisocytosis present. In all cases physical examination was negative, and the spleen was not palpable. In a necropsy on one fatal case a large haemorrhage into the medulla was found. All forms of treatment seemed equally unavailing, though vitamin dieting, calcium, serum and milk injections, and blood transfusion were tried. Although the patients at first sight appeared to be scorbutic, careful inquiry failed to elicit a real vitamin deficiency in the diet, and they did not improve on antiscorbutic diet. Some infection is suggested by the sudden onset and the occurrence of all five cases in the space of two months; but they came from different parts of the country, only women were affected, and there was no fever. David thinks that the cases belong to the ill defined class of haemorrhagic diatheses which have been divided by Frank into a true thrombopenia (morbus Werlhofii) and abnormal permeability of the capillaries due to a toxic agent in the blood stream (Henoch's purpura). Although his cases at first sight suggested the former condition, the onset was atypical; a fatal termination is rare in a true thrombopenia, and thrombopenia was least marked in his fatal cases. But they were not true Henoch's purpura, in which bleeding from the gums does not occur. He concludes that the present dual division of cases of purpura is inadequate, and suggests that in his cases an internal secretion may be at fault.

218. The Dick Test in Practice.

G. A. RADEMAKER (*Nederl. Tijdschr. v. Geneesk.*, September 18th, 1926, p. 1290) records his observations on the Dick reaction in the department for infectious diseases of the Municipal Hospital at The Hague, his conclusions being as follows. (1) The Dick reaction is an indication of the presence or absence of antibodies against scarlet fever, and therefore may be employed (*a*) in diagnosis of scarlet fever, (*b*) in the determination of the susceptibility to scarlet fever of healthy persons; this is of special importance for those coming in contact with scarlet fever patients, such as nurses, for children's homes, vacation colonies, and hospital wards. (2) A previously positive reaction is rendered negative in most cases by an attack of scarlet fever. This change confirmed the diagnosis in some doubtful cases before absolute certainty was obtained by other clinical symptoms such as desquamation, etc. (3) A negative reaction in the first four days of scarlet fever may occur (*a*) because the skin, although it previously gave a positive reaction, now possesses sufficient antibodies, (*b*) because the skin for the time being is not able to react. (4) A Dick reaction obtained in a susceptible person before the onset of the disease, or one obtained during the eruptive period and therefore not recognizable, is often manifested by the appearance of a white spot, showing that the formation of antibodies has taken place. (5) A previously

positive reaction on appearance of the eruption tends to flare up again at the same time as, or even before, the first signs of the disease, but before anything can be detected on the rest of the skin. (6) In 11 out of 278 cases the reaction remained positive after an attack of scarlet fever. (7) In all doubtful cases a positive reaction should be compared with a control reaction, to see if it is due or not to a pseudo-reaction which does not exclude susceptibility to scarlet fever. (8) Susceptibility seems to be less among the poor classes than among the well-to-do, as the chance of infection among the former is naturally much greater. (9) In 29 cases a positive reaction was found before the appearance of the eruption. Rademaker never saw a person with a negative reaction contract scarlet fever.

219. Typhoid Osteitis and Periostitis.

D. Y. KEITH and J. P. KEITH (*Journ. Amer. Med. Assoc.*, December 25th, 1926, p. 2145), who report three illustrative cases, maintain that typhoid bone infection is much more frequent than is indicated by statistics, as in a great number of cases suppuration does not occur. It is much more frequent in males than in females, because a larger percentage of males have typhoid fever, and owing to their occupation are more liable to injury to their osseous system. The complication may occur as early as the thirteenth day, or as late as forty-five years after the onset of the typhoid infection. Almost every bone in the skeleton may be affected, but the most frequent are those exposed to trauma—namely, ribs, tibia, spine, femur, humerus, ulna, foot, and clavicle. The infection may involve the medulla, periosteum, osseous tissue, and cartilage. Periosteal involvement is usually not so great as in syphilitic periostitis, and bone destruction is much less than in the metastatic staphylococcic bone-infection so frequently seen in the young. The typhoid spine shows very constant *x*-ray changes, which consist in destructive lesions in the bodies of the vertebrae with absorption of the intra-vertebral discs, which are thinner than usual and blurred. Later new bone deposits are seen around the vertebral bodies, with exostosis laterally to the spine, and with bony deposits in the vertebral ligaments. Clasp-like bone projections may be seen connecting the bodies of the vertebrae laterally.

220. Syphilis and Hypertension.

ACCORDING to WOLFF (*Dermatol. Woch.*, No. 52a, Bd. 83, 1926, p. 1911) the importance of high blood pressure in the later stages of syphilis has been unduly emphasized. He investigated 160 cases of syphilis: of these, 70 had been infected recently, 15 were cases of tertiary syphilis, 35 had old latent syphilis, 10 were congenital syphilitics, and 30 suffered from neuro-syphilis or parasyphilis. Only 20 of these patients (12.5 per cent.) had a high blood pressure. This is contrasted with Thom's series of 50 patients, all of whom had distinctly positive Wassermann reactions and very slight heart and kidney lesions; in 58 per cent. of the cases hypertension was found, and Thom concluded that the blood pressure was raised in more than 50 per cent. of all cases of syphilis. Among his 160 patients Wolff could not find a single case of definite "essential" hypertension. Although evidence of former syphilitic infection in elderly patients is often associated with cardiac, vascular, or renal lesions, these may be the result of senile degenerative changes, or be due to other infections. Wolff believes that the more virulent manifestations of syphilis in its early stages have greater influence in producing hypertension than have syphilitic lesions occurring more than a decade after the primary infection, and that the apparently essential hypertension of this later period is due to some obscure organic changes in the vascular system. He recommends accurate blood pressure observations in all stages of every case of syphilis.

221. Post-influenzal Heart-block.

A. S. HYMAN (*Med. Journ. and Record*, December 1st, 1926, p. 698) records three cases of heart-block — in a woman aged 28, a girl aged 18, and a man aged 63 respectively—illustrating the various degrees of conduction system depression following mild attacks of influenza. His conclusions are as follows. (1) Heart-block of the first degree with delay in conduction time from the auricles to the ventricles not infrequently follows a severe attack of influenza. (2) Heart-block of the second degree with intermission of the pulse due to dropped beats may follow a mild attack of influenza. (3) Heart-block of the third degree with complete dissociation of the auricles and ventricles may occur in an already badly damaged heart, as a result of an influenzal infection. (4) Myocardial damage following influenza bears no relation to the character of the original attack. In Hyman's experience the mild or unrecognized cases showed the most severe cardiac complications. (5) Electro-cardiographic studies of all cases having myocardial involvement following influenzal infection is suggested.

Surgery.

222. Traumatic Asphyxia.

H. E. CONWELL (*Journ. Bone and Joint Surg.*, January, 1927, p. 106) reports four cases of traumatic asphyxia, and considers that the condition is probably more frequent, as a possible complication of injuries to the chest and abdomen caused by sudden violent compression, either of prolonged or short duration, than study of the literature would suggest. Its occurrence immediately following an injury is characterized by marked violet, purple, or black discoloration, involving the head, face, neck, and shoulders to the level of the clavicles in front, and the lower border of the trapezius behind, though in some cases it extends lower and down the arm to the attachment of the deltoid. The discoloration is not always uniform in intensity, and apparently the more severe the injury the darker it is. There was a well marked line of demarcation in all Conwell's cases, and in one there was a band of normally coloured skin over an area covered by a tightly buttoned collar at the time of the accident. In all four cases there was bilateral subconjunctival haemorrhage. In fatal cases death is due to associated injuries, and is never apparently directly due to the asphyxia; in patients who recover the discoloration lasts only a few hours, though deep-coloured spots may remain for some time. The subconjunctival haemorrhages clear up slowly, and a guarded prognosis should be given as to sight, since optic atrophy has been reported. The condition is not due to an extravasation of blood, but to compression of the abdominal veins causing distension of the superior vena cava and its tributary veins and capillaries, the venous blood being forced into the capillaries of the face and neck. Treatment is that for shock, with artificial respiration, oxygen, and stimulants when necessary; patients who recover should be advised to wear coloured glasses.

223. Simulated Tuberculous Peritonitis.

O. WIEDHOPF (*Zentralbl. f. Chir.*, January 15th, 1927, p. 145) records an error in diagnosis in the case of a girl, aged 16, who had had an abdominal swelling with feeling of pressure for some months. The bowels were irregular and occasionally constipated; there was no vomiting, and the appetite was good. The chest was asymmetrical, the upper lobe of the right lung being smaller than that of the left. The breath sounds were generally harsh, with prolongation of expiration at the right hilus. The abdomen was very swollen and tense, with epigastric tenderness on pressure, but skiagrams failed to show any disease of the abdominal viscera. There was a family history of tuberculosis, and the patient stated that she had had a cough for two years, with frequent night sweats. A diagnosis of tuberculous peritonitis was made, and the patient was treated by *x* rays, but the abdominal circumference increased by 3 cm. in three weeks and the constipation became worse. In spite of the epigastric tension, several nodular masses could be felt. The urine contained indican. The patient's condition became worse, the abdominal circumference was 88 cm., and preparations were made for laparotomy. Under the anaesthetic the distension suddenly disappeared and the abdomen assumed normal proportions. No enlarged glands or exudate were found, nor was there any sign of intestinal tuberculosis. The appendix was removed. During narcosis, the abdominal circumference decreased from 88 to 76 cm. As the patient recovered from the anaesthetic the abdomen again became distended, so that there could be no doubt that it was a case of meteorism produced by muscular spasm, possibly of the diaphragm. When the wound had healed the abdominal circumference was found to be only 80 cm. The patient and her mother were informed that there was no tuberculosis and that the appendix had been removed. The patient made a good recovery, and when last seen the abdominal scar was firm and painless and the abdominal circumference was only 71.5 cm. The author adds that there is no doubt that neuropathic patients can produce abdominal distension by aerophagy and by active contraction of the diaphragm.

224. Fatal Embolism after Injection for Varicose Veins.

S. LOMHOLT (*Ugeskrift for Laeger*, January 6th, 1927, p. 7) reports a case of death following the treatment of varicose veins with saline injections, but remarks that an isolated fatality does not warrant the abandonment of a satisfactory treatment which has not caused similar disasters in the past. A man, aged 60, suffered from much dilated veins of the left leg. Some of the varices were very large, and though there were no scars, some eczematous patches were present. Five injections of 5 c.cm. of a 20 per cent. saline solution were given at short intervals and without any difficulty, the local reaction being no more severe than usual. On the day of the last injection there was slight tenderness and swelling of

a vein on the inner side of the thigh, and, consequently, the last injection was introduced into a very dilated vein over the Achilles tendon. Three days afterwards the tenderness in the thigh increased, and two days later the saphenous vein was found to be thrombosed up to the fossa ovalis; it was tender, and the skin over it was a little red. His temperature was 100.5° F., and he complained of pain in the right side of the chest. During the following days there were signs of recurrent pulmonary emboli, and a little over a month after the last saline injection had been given a new embolus caused death within an hour. The author has treated more than 100 cases in the same way without any pulmonary complications, and correspondence with K. Linser, whose name is associated with this treatment, elicited the information that in his knowledge no such accident had hitherto been recorded.

225. Ranula.

AS D. C. L. FITZWILLIAMS (*Brit. Journ. Surg.*, January, 1927, p. 472) remarks, "ranula" is a loose term which has been applied to all cystic swellings of the floor of the mouth. Ranulae may take origin in the mucous glands, the sublingual gland, Blandin's gland, and the submaxillary gland. These tumours first form in the mouth and then burrow into other regions. Fleischmann described a type originating in a bursa, but no one has been able to confirm his findings. With regard to the sublingual gland, it is often difficult to define the connexion between it and a ranula. Many ranulae are thought to arise in the submaxillary gland. There are congenital, acute, and traumatic ranulae, and those due to the blocking of Wharton's duct. Mucous glands are numerous under the tongue and are liable to become cystic, as is frequently seen on the lips. The conclusions drawn are that ranulae arise in the salivary glands and the mucous glands, but nowhere else.

226. Paraformaldehyde as a Surgical Disinfectant.

ELISE SANDERS (*Nederl. Tijdschr. v. Geneesk.*, January 15th, 1927, p. 349) performed a series of experiments with instruments and rubber gloves which had been infected with staphylococcal pus. They were left for twenty-four hours with a 1-gram tablet of paraformaldehyde, and a broth culture was then inoculated. The 70 tests with paraformaldehyde were all negative, whereas of 70 controls without paraformaldehyde 21, or 30 per cent., were positive. Sanders therefore recommends paraformaldehyde as a simple and cheap means of disinfecting instruments and rubber gloves.

Therapeutics.

227. Vaccine Treatment of Vulvo-vaginitis in Infants.

L. V. BLANCO and N. M. VILLAZON (*Amer. Journ. Dis. Child.*, December, 1926, p. 805) discuss the treatment by vaccines of gonorrhoeal vulvo-vaginitis in infants, giving notes of eleven cases—five treated with an autogenous vaccine and six with a stock vaccine. From a review of the literature and their own experience they consider that autogenous vaccines have undeniable curative properties enabling a condition hitherto tenaciously resistant to treatment to be cured in a relatively short time. The authors claim very good results, not only with autogenous but also with stock vaccines, provided that the organisms are derived from a female child. The vaccine is used in three series of six 1 c.cm. ampoules, each containing a mixture of gonococci, *B. coli*, staphylococci, and streptococci. The six doses of each series were injected within forty-eight hours, and there was an interval of eight days between the series, and bacteriological examinations of the vaginal discharge showed disappearance of the gonococcus and diminution in the colonies of other organisms. Of the eleven infants so treated ten were entirely cured; in six the cure was effected in from one to two weeks, in three in from two to four weeks, and in one in six weeks. The discharge diminished considerably a few days after the commencement of the treatment.

228. Treatment of Typhoid and Paratyphoid Fever with a Staphylococcal Vaccine.

V. BIE (*Acta Med. Scand.*, December 10th, 1926, p. 160) has during the past four years treated typhoid and paratyphoid fever with vaccines, giving a typhoid vaccine during the first two years, and a staphylococcal vaccine subsequently. By avoiding a specific typhoid vaccine he was able to start treatment at once, relying on a clinical diagnosis and without fear of interfering with the Widal reaction. The staphylococcal vaccine was given by intramuscular injection to avoid the comparatively severe reaction which may follow an intravenous injection, and the commencing dose was 100 million. On the four following days the injections were repeated and gradually increased, the dosage on the fifth day being 1,000 million. Rigors were a rare sequel, and there was never any collapse; the local reaction was insignificant. During the four years under review 51 severe cases of paratyphoid B, and 54 severe, or rather severe, cases of typhoid fever were thus treated. Among the 51 cases of paratyphoid fever there were 39 in which the temperature fell during or immediately after the treatment, this fall usually being by lysis. In four cases the fall of the temperature was more gradual, and in eight the treatment seemed ineffective, although none of these 51 cases terminated fatally. Among the 54 cases of typhoid fever there were 35 in which this treatment seemed beneficial. Seven of the patients died. The cases in which the treatment proved ineffective were usually complicated by pneumonia, and nearly all the uncomplicated cases responded satisfactorily to this treatment, which apparently shortened appreciably the duration of the disease. In this way the author suggests that he may have reduced the mortality of the disease, but he admits that his material is not sufficient to justify the claim on statistical grounds.

229. Tartar Emetic in Phagedaenic Ulcerations.

J. KINGSBURY and S. M. PECK (*Journ. Amer. Med. Assoc.*, December 4th, 1926, p. 1900) state that the intravenous use of antimony potassium tartrate in chronic infections was suggested by the germicidal action of arsenicals in syphilis, malaria, and trypanosomiasis since antimony belongs to the same chemical group as arsenic. The authors and others have shown that antimony potassium tartrate in fairly high [illegible]. Its external [illegible] uses so much [illegible] uble tartrate is best used in a 1 per cent. solution in 5 or 10 c.cm. ampoules. The sterility of the solution is assured by its germicidal power, and it should not be boiled, since this causes decomposition of the salt. The authors recommend an initial dose of 3 c.cm., so that the patient's sensitivity may be tested. This dose should be increased by 1 c.cm. at each injection till the maximum of 10 c.cm. is reached, and three or four injections a week may be given; they should be administered slowly, thus diminishing the tendency to a reaction. In phagedaenic ulcerations the authors find that treatment should be continued until almost complete epithelialization has occurred, and in granuloma inguinale it should be continued for several weeks longer to prevent recurrence. A few cases show reactions. A mild reaction is marked by coughing and salivation, and a severe one by cyanosis, gasping, and vomiting. Even in the latter case the benefits are so great that patients welcome treatment. The authors have obtained excellent results from this method in phagedaenic ulcerations of the genitals, and have found that it causes a rapid subsidence of the discharge, and prompt relief of pain and swelling in lesions refractory to other measures. It renders unnecessary local applications, which such complications as phimosis and balanitis render painful or difficult. They add that it should not be employed for simple chancroids.

230. Metal Salts in Pulmonary Tuberculosis.

H. LARSEN and K. TÖRNIN[illegible] uary 13th, 1927, p. 19) report from [illegible] ark, clinical experiments based o[illegible] who has recently shown that manganese and cadmium in certain doses greatly increase the concentration of antibodies in the blood of mice and guinea-pigs. The sanatorium observations ran parallel with the laboratory experiments, manganese being first given to a series of patients, and cadmium at a later stage, when its extraordinarily beneficial action in experimental animals was observed. From February, 1925, to May, 1926, intravenous injections of manganese chloride were given twice a week to 31 patients, of whom 4 were in the first, 9 in the second, and 18 in the third stage. As a rule, reactions occurred directly after the injections, consisting of congestion of the head, a rise of temperature, giddiness, headache, palpitation of the heart, and nausea. Tubercle bacilli were demonstrable at the commencement of treatment in 18 cases, and only in 3 did they disappear from the sputum. Of the 31 patients, only 12 showed improvement, whereas 12 showed no change and 7 became worse. Lunde published very encouraging results from treatment of patients in the third stage with injections of cadmium, 66 per cent. being rendered sputum-negative, but the present authors cannot confirm this experience. Since March, 1926, they have treated 10 patients with injections of cadmium, and in none could the claim be made that an improvement had been effected which could be traced to the treatment. They add, however, that even though the result of this investigation was entirely negative, no judgement on the suitability of this remedy in the treatment of tuberculosis in general is possible because the cases were too few and too severe.

231. Treatment of Malarial Bronchopneumonia.

G. CAUSSADE and A. TARDIEU (*Bull. Soc. de Thér.*, November 10th, p. 232), who record an illustrative case, remark that, in addition to acute bronchopneumonia, malaria may be responsible for chronic respiratory syndromes, among which may be included bronchitis, chronic fibroid pneumonia, chronic intestinal pneumonia, "sclerosis of the pulmonary framework with pigmentary infiltration or pneumo-paludism of Grall," and the pneumo-malaria of the apex of De Brun du Boisnoir. The authors' case was that of an Algerian native, aged 33, who had contracted malaria many years previously; he was suffering from subacute or chronic purulent bronchitis with congestion of the bases. The malarial nature of the attack was shown by the occurrence of typical malarial paroxysms during the course of the broncho-pulmonary attack. A rapid cure was obtained by the method advocated by Bretonneau and Trousseau of administration of powdered cinchona in daily doses of 10 grains, whereas the previous treatment, such as antipneumococcal serum, auto-vaccine therapy, and intratracheal injection of eucalyptol, had proved quite ineffective.

Neurology and Psychology.

232. Epidemic Polyneuritis with Meningeal Reaction.

M. ROCH and R. RICHEL (*Schweiz. med. Woch.*, January 1st, 1927, p. 18) report four cases of a condition which they have observed during the last two years, and regard as a new clinical entity. The disease begins suddenly with signs of infection which are sometimes ill marked but may consist of fever, headache, and sore throat. The attack would appear to be of little importance were it not for the fact that a neuro-meningeal syndrome develops simultaneously or shortly afterwards presenting the following features: slight and transient meningitis with spinal predominance; paralysis or paresis of varying site and extent with loss of the tendon reflexes, especially in certain muscle groups, and more frequently the proximal than the distal regions; an almost complete absence of sensory changes, which are represented merely by slight paraesthesia and spontaneous or provoked painful sensations connected with meningeal irritation; and a rapid course as soon as the motor symptoms develop, slow retrogression, and a favourable prognosis. The authors are inclined to regard the condition as related to epidemic encephalitis, for the following reasons: (1) Epidemic encephalitis is capable of producing lesions of the nerve roots, nerve trunks, and peripheral nerves. (2) Typical cases of peripheral forms have been accompanied by undoubted symptoms of encephalitis. (3) The clinical course of the polyneuritis is also in favour of an encephalitic nature. The manifestations vary from day to day, and are usually of long duration, but the cases generally have a relatively favourable prognosis. (4) The well recognized polymorphism of encephalitis. (5) The epidemiological character of the cases closely resembles that of epidemic encephalitis, the cases being sometimes sporadic and sometimes in groups. (6) The coincidence of the date of the appearance of the first cases of polyneuritis and those of the first cases of epidemic encephalitis in 1916–17. Subsequently cases of polyneuritis became increasingly numerous, so that it may be maintained with Crouzon that the character of Economo's disease underwent a change in that in 1917–18 lethargy and diplopia were usually seen, in 1919–20 neuralgia and myoclonus, and in 1925–26 motor polyneuritis. (7) Some striking cases in which contagion appeared possible. In the same family and in the course of six months a girl had encephalitis, her mother neuralgia and flaccid paraplegia, and her sister sensory changes with Babinski's sign and transient amaurosis. (8) The absence of any other disease to which the syndrome of epidemic polyneuritis could be attributed.

233. Hydrotherapy in Mental Diseases.

THE use of hydrotherapy in mental diseases is recommended by A. H. RING (*Med. Journ. and Record*, December 15th, 1926, p. 773), who gives details of the treatment and the indications. A prolonged bath at a temperature of 97° F. is sedative, regulates the circulation, and promotes elimination. In addition to its use in acute mania and chorea, it is beneficial in insomnia, asthenia, or cardiac conditions, if limited to about twenty minutes to an hour, according to the reaction and comfort of the patient. The wet pack is also useful as a sedative in conditions of excitability, and promotes nutrition by stimulating metabolism. Hot spinal fomentations are valuable as sedatives in mild cases of nervous disorder, and at night for insomnia; they are also useful in backaches and acute colitis. Simple shower or needle baths give mild stimulation, the degree of which can be increased by subsequent vigorous rubbing with table salt, followed by another colder shower. This leaves a very active hyperaemia and is a most valuable general tonic. For more robust cases and in alcoholic conditions a Scotch douche is preferable, the patient being placed in an electric light cabinet, with his feet in warm water and a towel wrung out in iced water upon his head, until profuse perspiration begins. A warm shower is then applied, followed by alternative hot and cold douches, beginning at the feet and slowly extending over the body. The pressure is increased for a few minutes so as to massage the tissues, and in this way an active and deep hyperaemia results, which greatly diminishes restlessness, produces a comfortable glow, and quickens metabolism. The author claims that, in dealing with sluggish or otherwise disturbed bodily functions and local congestions, which occur in nearly all nervous and mental conditions, there is no single measure so satisfactory as hydrotherapy.

234. Involuntary Movements in Tabes.

G. GUILLAIN, T. ALAJOUANINE, and L. GIROT (*Ann. de Méd.*, November, 1926, p. 530) remark that though a few writers, such as Cruveilhier, Trousseau, Leyden, Rosenbach, and Pierre Marie, allude to the occurrence of athetotic movements in tabes, no mention is made of them in most of the text-books of neurology. The present authors, who report four cases which they have observed at La Salpêtrière in the course of the last few years, describe the following three groups of involuntary movements in tabes, which differ in their character and situation, and in their relation to the other signs of tabes and to the evolution of the disease. The first group consists of movements which are mainly athetosiform, variable in character, non-rhythmical, and frequently set going by voluntary movements such as walking and diminished by rest. They are chiefly localized in the extremities, which present special deformities. They are associated with other signs of tabes, such as disturbance of tonus, superficial and deep sensibility and motility, and the presence of ataxia. The movements in the second group consist of a rhythmical tremor, diminished by rest and exaggerated at the end of a voluntary movement like an intention tremor. It affects the whole of the limbs and not the extremities only. The tremor is probably due to a focal syphilitic lesion in the mid-brain. The movements in the third group are of a chronic type and are confined to the face, tongue, and soft palate. In these cases there is probably a focal lesion involving the central tract in the mid-brain or certain adjacent motor tracts.

235. Mental Disease and Physical Form.

F. I. WERTHEIMER and FLORENCE E. HESKETH (*Medicine*, November, 1926, p. 375) observe that although some investigators have attempted to distinguish by anthropometry insane from normal individuals, yet it is extremely difficult in psycho-pathology to make a generic distinction between abnormal and normal. It appears certain that various psycho-pathological reactions are concerned in psychopathic personalities, and even in the behaviour of normal people. This is true also for the two commonest psycho-pathological reaction types—the manic-depressive and the schizophrenic. Modern researches have shown that there are no very significant differences in the quantitative incidence of mental disease in the ancestry of normal and abnormal individuals. The tendency of these modern studies has been increasingly to draw on all even slightly abnormal relatives, and finally on all members of the family. Despite the progress of modern heredo-biological psychiatric research, the knowledge of even a complete family history gives no clue to the pathogenetic factors of psychoses. For this study the authors consider that the modern dynamic and analytic point of view have proved more fruitful therapeutically, emphasizing the changeable psychogenic and environmental factors. The authors studied sixty-five male patients chosen without regard to diagnosis or physique, and found a certain correlation between morphological constitution, mental disease, and personality. They state that the pyknic (thick-set) types seem to occur more frequently in affective psychoses, while the more slender types are found to have schizophrenic psychoses and self-conscious personalities. Physical abnormalities are associated with schizophrenic reactions, and are undoubtedly traceable at times to certain endocrine disorders, such as those of the gonads and pituitary gland. The morphological and mental changes in cretinism and myxoedema are well known examples of endocrine etiology, but this subject has not yet been investigated by accurate anthropometric methods. The authors conclude that although structure and function may be assumed to be definitely related in the psychological sphere, yet both the extent and the nature of this relation are so far unknown. The use, therefore, of morphological constitutional signs in psychiatric diagnosis or prognosis is premature, although the occurrence of physical abnormalities may give some help in differential diagnosis.

Obstetrics and Gynaecology.

236. Treatment of Rigidity of the Cervix.

E. TONEFF (*Gynecol. et Obstet.*, December 6th, 1926, p. 384) states that in accouchements all interventions in dystocias should combine the minimum of risk with the maximum of benefit to both mother and child, and that dystocias of the maternal soft parts are twice as fatal to the infant as are those of the pelvis. Among the former rigidity of the os often occurs, even in patients with normal pelves and good uterine contractions, thus rendering dilatation slow and painful and labour very prolonged. Various writers describe two forms of cervical rigidity—the anatomical and the spasmodic. Toneff maintains that spasm of the uterine os is commoner than is thought, and is often the sole cause of the rigidity. This tetaniform spasm of the muscular fibres of the os may be either primary or secondary to some pathological condition, and is a great factor in causing long painful labour. With a view to exercising a sedative antispasmodic action on the rigid os Toneff has employed with excellent results belladonna or atropine, often combined with morphine, in the form of suppositories. He claims that chloroform has no appreciable sedative action on the uterus, an action markedly possessed by atropine, especially when used with morphine. The dosage recommended is about 1/4 grain of morphine with 3/4 to 1 grain of belladonna. No toxic effects to either mother or child have been observed. The author claims that this treatment, by abolishing the cervical spasm and rigidity, facilitates, quickens, and eases labour; that it should be administered as soon as the rigidity has been unmistakably diagnosed; and that the usual obstetrical interventions, whether by a bag, metallic dilator, bimanual manipulations, or Caesarean section, should not be employed until this simple therapeutic method has been used.

237. Quadruple Pregnancy.

D. ROSSI (*Rassegna internaz. de clin. e. ter.*, November 30th, 1926, p. 673) records an example of quadruple pregnancy in a woman, aged 38, who had had four children and two miscarriages by her first husband and two children and two miscarriages by her second husband. The quadruplets, which were born by podalic presentation, all died within a few hours of birth. Rossi has also collected 15 other cases of quadruple pregnancy from the literature from 1900 to the present day. In 11 of the 16 cases the pregnancy ended prematurely; in 1 there was placenta praevia, in 3 post-partum haemorrhage, and in 11 intervention was needed for difficult labour. Of the 60 foetuses born only 9 survived. The statistics of the frequency of quadruple pregnancy vary with the different writers. According to Veit there is one case among 388,000 births, and according to Patellani one among every 963,692 births. Brat-tröm found that one quadruple pregnancy occurred in Sweden every two or three years. According to Veit male foetuses are slightly more common than female in quadruple births. As a rule the mothers of quadruplets have had more pregnancies than the mothers of twins or triplets, and their average age (35 to 40) is higher. Examination of the foetal membranes shows that quadruple pregnancy is almost always due to fecundation of several ova and rarely to fecundation of a single ovum. In view of the fact that quadruple pregnancy is obviously related to a high multiparity, and especially to advanced age, a pregnancy of this kind may be regarded as a sign of sexual decadence.

238. Induction of Labour in Pelvic Contraction.

J. MCGIBBON (*Med. Journ. of South Africa*, November, 1926, p. 121) advocates the induction of labour for minor degrees of pelvic contraction, or of equivalent foetal oversize, as affording the nearest approach to normal labour, and in preference to Caesarean section. In the prevention of stillbirth induction is of value in avoiding the pathological results of excessive moulding. Except in those cases where the child is small McGibbon practises induction in all elderly primiparae a week or ten days before the expected date of confinement, and he thinks that Caesarean section should be reserved for extreme degrees of contraction and for elderly primiparae for whom it may be the last chance of having a living child. Prior to induction about 15 grains of quinine are administered daily for two or three days in order to sensitize the uterus, following which, by means of one or two fingers, the membranes are extensively detached from the decidua, usually producing a definite "show." This should be performed under an anaesthetic in primiparae, but in many multiparae no anaesthetic is needed. In cases where an unyielding os prevents the satisfactory detachment of the membranes by the finger alone bougies may have to be used. Induction of labour under rigid asepsis and with judicious selection of cases has an almost negligible maternal and and a diminishing foetal and neo-natal mortality; the method described is suitable in private practice. McGibbon recommends that the premature infant should be treated for one month in a maternity hospital.

239. Maintenance of the Foetal Heart Beat during Labour.

E. SPIER (*Med. Klinik*, December 3rd, 1926, p. 1885) advocates cardiac stimulants and general anaesthesia in cases of foetal distress where the heart beat is below 100 or over 160 during several intervals between pains. If quick delivery is possible ether anaesthesia alone will quicken the slowed foetal heart and maintain it during spontaneous or forceps delivery. More difficult are the cases in which the foetal heart is failing before forceps can be applied after Caesarean section is advisable. The usual cause of intrauterine asphyxia and foetal death is disparity between the size of the head and the pelvis, and it may also be due to abnormally strong pains. It is seen mainly in the case of a flat pelvis with a large child, or a normal pelvis and a post-mature child. Poeck has treated four cases successfully by giving the mother intravenous injections of cardiac stimulants, and in one case a similar injection was made into the caput succedaneum just before applying forceps. Spier reports a case in which the foetal heart was 80 between the pains and slower during them; it was irregular, and meconium was being passed. Strophanthin was given intravenously and ether anaesthesia begun. Half a minute after the injection the foetal heart increased to 120 and became regular, and anaesthesia was maintained until forceps delivery was possible (1 hour 10 minutes). The heart beat remained regular at a rate of 120, except when the anaesthesia was light enough to allow of strong pains, when it slowed again. The child was blue on birth, but revived quickly. Spier prefers ether to chloroform, because it can be kept up longer and the dosage better regulated; its slower induction is compensated by giving strophanthin to maintain the heart until anaesthesia is complete.

240. Gonorrhoea in Pregnancy.

E. V. DAVIS (*Urol. and Cutan. Rev.*, December, 1926, p. 710) states that the incidence of gonorrhoea in pregnant women during his thirty years of obstetrical work has been about 22 per cent. and that of syphilis about 3 per cent. Neglected gonorrhoea in women may lead to mixed infections and involve the uterus, tubes, and ovaries to such an extent that sterility is the usual sequence. Laboratory findings should not determine the diagnosis, since a chronic gonorrhoeal discharge is often mistaken for leucorrhoea. The best plan is to examine the patient several times during her pregnancy. If the discharge is not due to chronic gonorrhoea it will clear up under proper douching in a few days; if it is due to gonorrhoea it will be more stubborn and will return if the treatment be neglected. The treatment consists in simple vaginal douches of mercury perchloride 1 in 4,000, twice daily in active cases, and once daily as soon as the discharge begins to disappear. After it has ceased the douches are given every other day and then twice a week, but the patient should be under observation until the time of her delivery. If the discharge recurs after a day or two without treatment the initial treatment is resumed. In cases so treated ophthalmia neonatorum is very rare. As soon as the infant's head is born the eyes are wiped with dry sponges, and 1 per cent. silver nitrate solution is instilled into them soon after birth. The entire body is then washed in a bath of 1 in 10,000 mercuric chloride solution, and the child is placed in a sterile blanket.

Pathology.

241. Transmutation of Pathogenic Cocci?

MORGENROTH and his co-workers asserted that by growing pneumococci in a medium containing optochin they were able to transform them into streptococci of the *viridans* group, but H. A. REIMANN (*Journ. Exper. Med.*, January, 1927, p. 1) has repeated this work, but has been unable to confirm their results. A Type I pneumococcus was grown in serum broth containing a sterilized suspension of dried yeast on to which optochin hydrochloride (ethyl hydrocupreine hydrochloride) had been absorbed. After three subcultures plates were made, and a number of small thin colonies with a rough surface, similar to the "rough" type of pneumococcus observed by other workers, appeared. Similar results were obtained when the organism was grown in broth containing optochin alone or in serum broth containing yeast alone. These rough colonies are similar to those which were obtained by Morgenroth and

considered as true *Streptococcus viridans* colonies. The present author, however, believes that they are not streptococci but rough varieties of pneumococci, since they are soluble in bile, though not so readily as the ordinary variety of pneumococci, and they can be dissolved by a 2.5 per cent. solution of sodium taurocholate provided a saline suspension is employed. If a broth suspension is employed a 2.5 per cent. solution is unsatisfactory, but higher concentrations of taurocholate will effect lysis. These organisms also undergo autolysis very easily, which streptococci do not. Saline suspensions of six strains of the rough pneumococci when incubated at 37° C. for forty-eight hours were completely autolysed; similar suspensions of ten strains of *Streptococcus viridans* were not autolysed in this time. Moreover, the immunological reactions of the rough pneumococci obtained by Morgenroth's method were identical with those of rough pneumococci obtained by other methods. An attempt was also made to convert *Streptococcus haemolyticus* into *Streptococcus viridans* by growth in serum broth containing rivanol. Morgenroth claimed that he had been successful in this. In spite, however, of attempts made with twenty-six strains of haemolytic streptococci, about 400 transfers being made, Reimann failed to effect this transformation.

242. Graphic Representation of the Pressure of the Cerebro-spinal Fluid.

S. TZANCK and P. RENAULT (*C. R. Soc. de Biologie*, January 21st, 1927, p. 81) have devised a simple method for registering the pressure of the fluid in the subarachnoid space. A lumbar puncture is performed in the usual way with the patient in the recumbent position. Attached to the needle is a rubber tube, fitted apparently with a three-way tap by which it is possible to lead off the cerebro-spinal fluid to a tube for collection, or to put it into communication with a manometer, or to arrange for the reinjection of air into the spinal canal. As soon as the needle is in position the pressure of the fluid is noted; then 1 c.cm. is withdrawn at a time, the pressure being determined after each portion, till 10 c.cm. have been removed. A graph is then plotted with the amounts withdrawn along the ordinates and the pressures along the abscissae. In a normal person the resultant curve is a horizontal line on which undulations due to coughing, muscular effort, and other disturbing factors are apparent. The pressure, which corresponds to 15 c.cm. of water, remains stable. In pathological conditions the actual pressure may be different and the curve is no longer horizontal. For example, if the withdrawal of the fluid is accompanied by a rapid fall in the pressure, an encysted meningitis or a meningeal tumour may be present. If, on the contrary, the pressure is high and is not lowered by the withdrawal of 10 to 20 c.cm. of fluid, it is possible that the subarachnoid spaces are distended, as may happen in tuberculous meningitis. Such observations may be made in the absence of any chemical or cytological alterations in the fluid.

243. Plasma Proteins in Health and Disease.

H. A. SALVESEN (*Acta Med. Scand.*, December 10th, 1926, p. 147) refers to the work of Rowe, Epstein, Robertson, and others, and states that there is considerable variation in the concentration of plasma proteins and in the relation of albumin to globulin. As the result of examining sixteen men and sixteen women, whose ages ranged from 23 to 40, he found in the men an average total protein content of 7 per cent., the albumin averaging 4.44, the globulin 2.58 per cent., and an albumin-globulin ratio of 1.72. In the women the total protein averaged 7.02 per cent., the albumin 4.35, the globulin 2.68 per cent., and the ratio 1.62. Repeated determinations in the same individual showed considerable variations in the total protein as well as in the ratio. Salvesen states that in nephrosis, in which the changes in the plasma proteins are most pronounced, the albumin fraction is usually very low, while the globulin fraction is but little diminished or even slightly increased; instead of the normal concentration of about 7 per cent. of plasma proteins, values of 4 per cent. or even less are found with a low ratio. The author reports a case of this disease (ibid., p. 152) in which opposite conditions obtained, the total proteins being increased to 10.73 per cent., the globulin to 8.32 per cent., while the albumin (always greater than globulin in normal plasma) decreased to 1.9 per cent., and the ratio to 0.23. The usual symptoms of hypertension, eye changes, haematuria, pronounced functional disturbances, and oedema were absent, but the protein excretion was high. Discussing the case, Salvesen states that a plasma protein increase of nearly 50 per cent., and the increase found in the globulin, have not been previously reported in Bright's disease. The loss of albumin from the blood through the urine was evidently repaired by the production of globulin in such large amounts that the result was a total plasma protein increase; the absence of oedema supports the theory of the causal relation between hypoproteinaemia and oedema production. According to this theory there should be no cause for increased diffusion of water from the blood in this case, as the osmotic pressure of the plasma protein was not lowered.

244. The Action of Cyanides on Bacteria.

NUMEROUS biologists have reported that potassium cyanide inhibits growth by interfering with the oxygen uptake of the cell, and F. M. BURNET (*Journ. Path. and Bact.*, January, 1927, p. 21) finds that though it has little direct disinfectant action on bacteria it is able, in comparatively low concentrations, to prevent their growth. Some organisms were sensitive and others insensitive to small amounts of cyanide. The sensitive organisms included the coliform group, staphylococci, the diphtheroid group, *B. pestis*, *B. melitensis*, *B. subtilis*, *V. cholerae*, and the meningococcus. The chief members of the insensitive group were the streptococci and the pneumococci. On glucose agar the sensitive organisms were inhibited by a concentration of 0.04 to 0.1 per cent. of cyanide, while the others required a concentration of 1 to 2 per cent. It was found that though the members of the first group were unable to grow aerobically in glucose agar containing cyanide they were able to grow anaerobically. The two groups are distinguishable also by other characteristics. Thus the members of the first group are sensitive to low concentrations of hydrogen peroxide; members of the second group are not, and some can form peroxide during growth, which none of the organisms of the first group can do. On the other hand, most organisms of the first group form catalase, which none of the second group can produce. The author concludes, therefore, that these two groups of organisms possess different respiratory mechanisms. He suggests that the bacteriostatic effect of potassium cyanide on the members of the first group is due to a lowering of the upper limit of oxidation potential within which they are able to develop.

245. Tissue-digesting Enzyme (Histase) of Streptococci.

M. FROBISHER (*Journ. Exper. Med.*, December, 1926, p. 777) has demonstrated the presence of an enzyme capable of digesting ox or human heart muscle in a number of streptococci —mostly of the β-haemolytic type, using Holman's modification of Robertson's cooked meat medium. Digestion, which was manifested by the subsidence of the meat in the tubes, was evident after forty-eight hours' incubation at 37° C.; after five days about 30 per cent., and after thirty days about 75 per cent. of the meat had been digested. The enzyme responsible for digestion is present in Berkefeld filtrates of the cultures; it was partly inactivated by exposure to 60° C. for one hour. There was no absolute correlation between the power to digest meat and the ability to haemolyse rabbit's blood; some strains produced a haemolysin but no histase, and one strain among twenty-two studied secreted a histase but no haemolysin. Some of the histase-producing strains digested casein, but none of them had any action on gelatin or blood serum. Formol titrations showed that in meat cultures undergoing digestion there was an increase in the amino-acid content of the fluid portion of the medium. The enzyme, which closely resembles trypsin, has not hitherto been described, and the author thinks that owing to the ease with which it can be demonstrated it should prove useful in the identification and possibly the classification of streptococci.

246. Production of Tetanus Anatoxin by Growth in Bile Broth.

G. RAMON, A. BERTHELOT, E. GRASSET, and Mlle AMOUREUX (*C. R. Soc. de Biologie*, January 14th, 1927, p. 30) report that if the tetanus bacillus is grown in broth to which ox bile has been added an anatoxin is formed directly which can be detected by the Ramon flocculation test. In their experiments a strain of tetanus bacillus was grown in broth to which quantities varying from 1 to 7 per cent. of bile had been added. After twenty-five days' incubation the cultures were filtered and the filtrates tested for their toxicity to guinea-pigs. The results showed that the 1 per cent. bile-broth filtrate was fatal in a dose of one-thousandth of a cubic centimetre, while the 7 per cent. bile-broth filtrate was not fatal even in a dose of 2 c.cm.; the remaining filtrates showed values intermediate between these two. It might have been concluded that the bacillus had failed to form a toxin in the 7 per cent. bile medium; but when this filtrate was examined by the flocculation test it was found to give a strong reaction, showing that the antigenic component of the toxin had been formed. Judged by the flocculation test all the filtrates from cultures in bile broth were of approximately the same strength, and all were two or three times as strong as filtrates from plain broth cultures. It would appear, therefore, that by growth in broth containing about 7 per cent. of bile it is possible to obtain an anatoxin directly.

EPITOME OF CURRENT MEDICAL LITERATURE.

Medicine.

270. Spirochaetosis Icterohaemorrhagica.

P. C. CLEYNDERT, jun. (*Nederl. Tijdschr. v. Geneesk.*, January 29th, 1927, p. 562), refers to the fourteen previous cases of this disease reported in Dutch literature (see *Epitome*, October 10th, 1925, para. 288; June 19th, 1926, para. 612; August 7th, 1926, para. 91; October 16th, 1926, para. 343; November 6th, 1926, para. 418) and reports a fatal case in a man, aged 33, who had been a regular attendant at the municipal swimming baths at Gouda. Although *Leptospira icterohaemorrhagiae* was not found on section of the organs, the clinical course and the positive result of the serological examination left no doubt as to the diagnosis. As the patient had presumably become infected in the swimming bath, Cleyndert made an inquiry as to whether other visitors to the bath had had a similar illness, and found that a man aged 23 and a girl aged 21 had both had fever, headache, and pains in the calf muscles, the agglutination test being positive in both cases. Cleyndert also thinks it probable that the swimming bath instructor, who had died some months previously of what was diagnosed as purpura fulminans, was really suffering from spirochaetosis icterohaemorrhagica, but no serum test was performed. Like Kramer and van Gelder, he maintains that Weil's disease has been more prevalent in Holland, at least in the last two years, than is generally supposed, and that it is not always so benign as German publications would suggest. According to Schürer the mortality ranges from *nil* to 30 per cent., the average being 7.4 per cent. Of the eighteen Dutch cases now on record five were fatal—a mortality of 27.8 per cent. The Gouda bathing establishment is in the middle of the town, close to the cattle market, and is infested with rats. Examination of the bath water and of rats found both in the swimming bath and elsewhere in Gouda showed the presence of the leptospira. As the result of Cleyndert's advice the swimming bath was closed.

271. K. M. HAYMAN, jun., and F. B. LYNCH, jun. (*Amer. Journ. Med. Sci.*, January, 1927, p. 80), who record a typical case in a labourer aged 42, with a review of the literature, maintain that Weil's disease is of sufficiently frequent occurrence to warrant the consideration of that diagnosis in any illness of sudden onset with headache, generalized pains, exhaustion, vomiting, conjunctival congestion, herpes labialis, a temperature of 103° or 104°, and jaundice appearing on the third or fourth day. A positive diagnosis requires the demonstration of *Leptospira icterohaemorrhagiae* in the blood and urine, preferably by guinea-pig inoculation. The organism, as a rule, is not present in the blood after the seventh day. Apart from the use of convalescent serum and an artificially prepared antiserum the treatment is wholly symptomatic.

272. Chronic Dysentery.

H. KOOPMANN and E. KRÜGER (*Med. Klinik*, December 24th, 1926, p. 1993), from a study of eighty cases of chronic dysentery at Hamburg, came to the following conclusions: (1) Infection with chronic Y dysentery is very prevalent, especially in young persons and tuberculous subjects. The transmissibility of the disease, although proved, is not great. (2) The Widal test may be regarded as conclusive in the diagnosis of chronic dysentery. (3) The sites chiefly affected by dysentery bacilli where they may remain latent for a long period are the gall bladder, pancreas, and appendix. (4) Chronic dysentery is a relatively harmless disease which is very amenable to treatment, although occasionally it may be a very obstinate complaint. (5) Of the therapeutic methods for the treatment of chronic dysentery oral administration of a yoghurt preparation known as "Imbar 6" is said to be the method of choice.

273. Cancrum Oris in Unrecognized Scarlet Fever.

H. AUDEOUD (*Rev. méd. de la Suisse romande*, October 25th, 1926, p. 824) reports a case, in a boy aged 2½ years, admitted to hospital with oral fetor, gangrene of the upper gum margin, and necrosis of the upper jaw with loss of the four upper incisors. In the lower jaw only the right portion of the bone was involved, with loss of the second incisor and canine. The cheeks, palate, and pharynx were unaffected. Cultures yielded streptococci and staphylococci only, and no Vincent's or Schimmelbusch's organisms were found. The hands and feet showed well marked desquamation, which justified a retrospective diagnosis of scarlet fever, especially when it was found that the child had had a sore throat and a generalized rash nine weeks previously. Under local treatment with novarsol, potassium permanganate, and tincture of iodine, accompanied by subcutaneous injections of collargol, camphor oil, and strychnine, gradual improvement occurred, but the child lost sixteen of the twenty milk teeth and an indefinite number of the permanent set. Recovery finally ensued, but considerable deformity of the gums resulted.

274. Clinical Varieties of Scarlatinal Nephritis.

S. LEFEBVRE (*Thèse de Paris*, 1926, No. 563) describes three varieties of nephritis in scarlet fever. In the very acute form, which is associated with the onset of malignant scarlet fever, the urine is scanty, dark, loaded with albumin, and sometimes there is complete anuria; haematuria is frequent. The prognosis is generally fatal. According to different observers early nephritis may be a rare, or an almost constant, phenomenon. It is most frequent in cases with a high temperature and severe angina, but may be found in the mildest attacks. It has been noted in a little more than half the fatal cases. Late nephritis chiefly appears between the fifteenth and the twenty-fifth day, and is very often accompanied by a recurrence of fever and other complications, such as angina, adenitis, and joint affections. In Lefebvre's experience the majority of cases of scarlet fever are not complicated by any renal lesion. Among his 191 cases there was not a single one which was complicated by typical scarlatinal nephritis, but there were a few examples of transient febrile albuminuria.

275. Pollen Toxaemia in Children.

I. S. KAHN (*Journ. Amer. Med. Assoc.*, January 22nd, 1927, p. 241) finds that in hay fever and asthma in children there is very slight alteration in the general health, even over extended periods, in most cases. In some children, however, there is not only the physical discomfort, but also a condition due to toxaemia. The differential diagnosis from other toxaemias is established by appropriate laboratory measures and by treatment designed to relieve hay fever and asthma. The etiological factor is usually combined pollen and feather sensitiveness. The children present a picture of continuous catarrh, and the characteristic attacks of hay fever are unusual. The chronic catarrhal condition suggests tonsil and adenoid obstruction, but excision does not give relief. The patients appear to be sickly, with deficient growth and weight, and they are mentally backward. The facies is sallow and suggests that of congenital syphilis. The nasal mucosa is typical of vasomotor rhinitis. The chest is barrel-shaped, and emphysematous râles are present. Cardiac enlargement and murmurs are not found. Eosinophilia is an uncertain symptom, but a lymphocyte increase is not unusual. The most outstanding peculiarity of the disease is the mental condition, and, in severe cases, the extreme psychical alteration, listlessness alternating with spells of intense temper and easy weeping on the least provocation. Within a few weeks, or even days, following desensitization and pollen precautions, the entire picture changes and there is a rapid approach to normal; especially is this the case mentally. Desensitization treatment is usually long and tedious, but ordinarily succeeds in the long run.

276. Clinical Characters of Variola.

S. E. SWEITZER and K. IKEDA (*Arch. Derm. and Syph.*, January, 1927, p. 19) record their observations on the small-pox epidemic at Minneapolis which persisted throughout the whole of 1924 up to September, 1925, during which time there were 1,430 cases with 365 deaths—a mortality of 25.5 per cent. In none of the fatal cases had vaccination been performed successfully within the last seven years. In 71 cases successful vaccination had been performed more than seven years before, 279 had never been successfully vaccinated, and in the remaining 15 cases no history was obtained. During the epidemic 581 small-pox patients were admitted to the Minneapolis General Hospital, of whom 246, or 42 per cent., died; 10 were of unclassified type with no deaths; 225 were discrete cases with 14 deaths, a mortality of 6 per cent.; 151 were confluent cases with 68 deaths, a death rate of 45 per cent.; 144 were haemorrhagic pustular cases with 113 deaths; and 51 were purpuric cases, all of which were fatal. Of these, 29 had only a diffuse purpuric eruption and 22 had a papular eruption also, which was usually scanty, erythema, petechiae, and ecchymoses being the predominating clinical manifestation. The blood in the pustular stage showed a leucocytosis with a relative lymphocytosis and a high platelet count. The authors state that in purpuric small-pox there is hyperleucocytosis as a rule, with an absolute

lymphocytosis and a persistently low platelet count. They found fragmentation and condensation of the nucleus of the polymorphonuclear cells, while normoblasts, basophilic stippling, and polychromatophilia were present without evident anaemia. Various remedies, including serum, mercurochrome-220 soluble, gentian violet, and neo-arsphenamin, were tried, but none proved of any value.

277. Typhoid Meningitis.

A. SCHWEISGUT (*Klin. Woch.*, January 29th, 1927, p. 215), who records an illustrative case, states that after discovery of the typhoid bacillus it was expected that the organisms would be found in the meninges and cerebral lesions, and so explain the occurrence of meningitis in typhoid fever. Such a finding, however, proved to be extremely rare. Typhoid meningitis was accordingly attributed to toxins, and purulent meningitis in typhoid fever was said to be due to a mixed infection. Staubli in 1905 made the following classification of meningeal involvement in typhoid fever: (1) typhoid meningism, which he regarded as frequent; (2) serous meningitis or purulent meningitis due to mixed infection; (3) very rare cases of meningeal suppuration due to typhoid bacilli only. Subsequent publications, including records of cases examined histologically during the war, showed that true purulent typhoid meningitis without mixed infection was exceptional. Schweisgut's case was that of a lad, aged 18, admitted to hospital with typhoid fever and signs of meningism. As the intestinal condition improved cutaneous and intestinal haemorrhages developed, followed by purulent spinal meningitis, which dominated the clinical picture and was the cause of death. A pure culture of typhoid bacilli was obtained from the purulent cerebro-spinal fluid. In addition to the purulent meningitis the necropsy showed healing typhoid virus in the intestines.

Surgery.

278. The Surgery of Gastro-Duodenal Ulcers.

J. M. T. FINNEY (*Amer. Journ. Surg.*, December, 1926, p. 323), after relating the history of the surgical treatment of these conditions, states that experienced surgeons prefer to follow a middle course in dealing with these lesions. They make use of the more conservative types of operation and reserve the more mutilating methods for exceptional cases. In view of the danger of perforation, haemorrhage, and malignant changes it would appear that resection of the ulcer is indicated. Pyloroplasty or gastro-duodenostomy, associated where possible with resection of the ulcer, would be the first choice, while gastro-enterostomy or extensive gastric resection would be relegated to second or third choice. Extensive resection of the stomach is reserved almost entirely for malignant disease. The risks of this procedure in the hands of the average surgeon appear to contraindicate its general adoption. In the treatment of perforation gastro-enterostomy should be reserved only for cases where pyloric stenosis or multiple ulcers are present. Cases treated by simple suture do as well or better than those in which a gastro-enterostomy is performed. The best end-results in gastric surgery will be obtained if the surgeon keeps an open mind, establishing first the facts and then performing that operation which in his judgement is best adapted to the conditions found.

279. Thoracic Stomach.

MENTIONING the great rarity of the condition R. E. ROBERTS (*Brit. Journ. of Radiol.*, January, 1927, p. 17) records the case of a patient whose stomach developed above the diaphragm instead of below it. The patient was a girl aged 3 years and 10 months; the family history was unimportant. Except that she was constipated and undersized, no special abnormality was noted until she was a year old, when she began to vomit milk and food, especially if fatty. This vomiting increased in severity and sometimes occurred immediately after ingestion, at other times after the interval of an hour or more. At the age of 2 there was vomiting of the ejaculatory type at every meal. Some of the food was always retained and there was no great constitutional disturbance; small meals were best tolerated. There was no chest pain, and although after meals her breathing was difficult, she was never cyanosed. By *x*-ray examination the stomach was found lying above the diaphragm in the posterior mediastinum. The gullet was short and the cardiac orifice was situated at the fourth costal cartilage in the middle line. There was no oesophageal obstruction. The pylorus occupied an opening in the right leaf of the diaphragm below the eleventh rib. Immediately after the examination by opaque meal the patient vomited, but on subsequent examination a portion of the meal was found in the intestines, after having been seen to pass through the pylorus.

280. Lumbo-sacral Backache.

C. E. AYERS (*Boston Med. and Surg. Journ.*, January, 1927, p. 9) gives an account of recent work on lumbo-sacral backache, with reports on a series of cases treated by fusion operations. He believes that lumbo-sacral arthritis as a cause of pain in the back is of more common occurrence than has been supposed, and that the production of ankylosis is probably the best form of treatment. Congenital abnormalities of the fifth lumbar vertebra are far from rare, and it is possible that sacralization of the lumbar vertebrae may be the cause of persistent pain. In diagnosis the lateral *x*-ray examination of the lumbo-sacral region is absolutely essential, and in cases where the *x*-ray findings do not confirm the clinical diagnosis the examination of the bones at the fusion operation will establish the nature of the condition. The fusion operation is not accompanied by shock, and, suitably conducted, is not a dangerous procedure.

281. Recurrent Post-typhoid Osteitis.

A. DUFOURT and ALOIN (*Lyon méd.*, January 7th, 1927, p. 42) report the case of a girl, aged 20, who, nine months after an attack of typhoid fever, developed osteitis of the right humerus, and three and four months subsequently osteitis of the left ankle and right ribs in the submammary region. Nine months afterwards right otalgia and otorrhoea ensued, complicated three months later by signs of meningitis. A clear sterile fluid under hypertension, containing an excess of albumin, was removed by lumbar puncture. On operation pus was evacuated from the mastoid process and numerous pockets in the petrous portion of the temporal bone. Death in coma occurred four days after the operation. Cultures of the carious petrosal bone showed typhoid bacilli associated with streptococci. The cerebro-spinal fluid was sterile but agglutinated the typhoid bacilli in a dilution of 1 in 500. This case is thought to be the first on record of typhoid osteitis of the petrous portion of the temporal bone. The authors emphasize the importance of vaccine treatment in typhoid osteitis, especially at an early stage, when it may prevent the necessity of a surgical operation. In the present case this treatment was not employed.

282. Fragilitas Ossium.

J. J. SHUGRUE, R. ROCKWOOD, and E. W. ANDERSON (*Arch. Intern. Med., January 15th, 1927, p. 98*) report four cases of fragilitas ossium, the patients having blue sclerotics, brittle bones, and deafness; in one case the Mendelian type of familial transmission was clearly shown. The disease is hereditary, and one, two, or all the symptoms may be present. Children with blue sclerotics alone affected usually die in infancy, but when this coloration manifests itself in adolescence brittle bones are also present, and deafness due to oto-sclerosis may occur later. The fractures may be spontaneous or the result of trauma, and *x*-ray examination shows bone atrophy. It is thought that such cases are the result of a congenital mesenchymal defect, and though this theory does not explain why other tissues of mesenchymal origin are not affected, one of the author's patients had an associated cardio-vascular degeneration. The disease is said to be rare and progressive, but is concomitant with longevity. The colour of the sclerotics was uniform in all cases, the homogeneous leaden blue being seen through the scleral conjunctiva in whichever direction the eyeball was turned.

283. Prevention of Rheumatic Arthritis by Removal of Septic Foci.

IN view of the failure of salicylates to prevent relapses following acute rheumatism ÖSTEN HOLSTI (*Acta Med. Scand.*, January 26th, 1927, p. 352) has tried prophylactic treatment of the inflammatory processes in the upper respiratory passages in 35 cases of acute and relapsing rheumatic arthritis. No surgical procedure was attempted, as a rule, before the patient had completely recovered from the acute rheumatic attack. Before a tonsillectomy the rate of coagulation of the blood was determined in most cases, and calcium was administered when considered necessary. The examination of the teeth and the treatment of all inflammatory conditions in the mouth were dealt with in a dental clinic. Among the 35 patients, whose ages ranged from 10 to 60 years, there were 13 males, and as many as 28 were between the ages of 15 and 25. The average period of observation was four and a half years, and the author was able to follow up every case. The course of the disease after treatment of the inflammatory processes in the upper respiratory passages was classified as follows: (1) Two patients died. (2) In 3 cases relapses, similar to those before the treatment, occurred; two were not purely rheumatic, one patient having gonorrhoea, and the other haemophylia. (3) In 4 cases occasional swellings of the joints occurred without fever or disturbances of the general condition. (4) In 9 cases minor rheumatic manifestations, such as pain without swellings of the joints appeared. (5) Three patients continued to have slight attacks of sore

throat, 4 suffered from recurrent colds in the head, one developed pulmonary tuberculosis, one hay fever, and two had recurrent attacks of urticaria. (6) In 14 patients the general health remained poor, although there were no well defined signs of disease. (7) Good health was maintained in 19 patients, of whom as many as 14 had had two or more attacks of rheumatic disease of the joints, while 5 had had only one attack when treatment was first instituted. During the observation period of four and a half years there was not one patient, among those who had reached puberty, who suffered from a relapse of the purely rheumatic condition after treatment had been instituted. He considers it possible that the treatment modified the course of the disease, the removal or reduction of septic foci preventing relapses or diminishing their severity to a marked extent.

284. Congenital Dislocation of Both Knees.

J. GROSSMAN (*Med. Journ. and Record*, February 2nd, 1927, p. 189) describes two forms of this condition. The first is a hyperextension of the knee rather than a true dislocation, with no marked displacement of the tibia or the femur. The second is a true dislocation, in which the condyles of the femur are displaced backward in their relation to the tibia. It is suggested that this deformity is the result of compression in the uterus with the knee in a bad position. Congenital dislocation of the hip, also supposed to be caused by pressure, may accompany the knee condition. Grossman reports one case of the second type in an infant a week old. Both knees were hyperextended and the knees could be further extended passively until the anterior surfaces of the thighs and legs came into contact. The patellae could not be felt. The condyles of the femur could be palpated in the popliteal region, being displaced backward in their relation to the tibia. The hips were normal. Treatment consisted in manipulation into the straight position and the subsequent application of circular plaster-of-Paris bandages. This was continued over a period of four months, when the patient was discharged cured.

Therapeutics.

285. Gold Salts in the Treatment of Psoriasis.

G. HUFSCHMITT (*Paris Méd.*, January 22nd, 1927, p. 91) has tried the effect of "triphal" and sanocrysin (salts of gold) in 12 cases of psoriasis. There appeared to be no difference in the therapeutic action of the two preparations, and except in one case of erythrodermia and one of slight albuminuria no ill effects were noted. The ages of the patients ranged from 16 to 58 years, and the duration of the disease from some months to several years. The initial dose was 0.005 gram of triphal and 0.05 gram of sanocrysin. Two of the patients ceased treatment after the tenth injection as no benefit appeared. In three cases the pruritis disappeared after the fourteenth injection and the eruption was improved. In seven cases the success was complete, with total disappearance of the rash, and no recurrence after six months. The author adds that where there is extensive dermatosis, red and very squamous, the treatment is contraindicated.

286. Injection Treatment of Varicose Veins.

V. MEISEN (*Ugeskrift for Laeger*, January 20th, 1927, p. 47) analyses his experience, during the past twelve months, of 500 cases of varicose veins treated by injections of equal parts of a 25 per cent. solution of sodium salicylate and of a 10 per cent. solution of sodium chloride. The maximum quantity of this solution given at one injection in the most recent series of cases was 10 c.cm., the patient standing on both feet till the point of the needle was within the lumen of the selected vein. The patient was then made to lie down, and the vein allowed to empty itself of blood before the injection was started. This was given slowly and was interrupted at once if it caused pain. In cases in which pain was anticipated, a preliminary injection of a 0.5 per cent. solution of novocain, containing no adrenaline, was given. When the saline injection was completed and the needle withdrawn, the site of the injection was gently massaged and then compressed with a gauze pad which was firmly secured with an elastic bandage while the leg was still raised. Altogether 2,224 injections were given, and in the most recent series of cases the average of four or five injections per case was increased to a greater number. The patients included 130 males and 370 females, their ages ranging from 15 to 81. Advanced age was not found to be a contraindication. In 135 cases the varicose veins were complicated by ulcers, and in 40 by chronic eczema. In all but two cases the sores were healed on the patient's discharge, and only in a few did the ulceration recur. In 14 cases (3 per cent.) operative treatment had been attempted and had proved unsatisfactory. In no case did the injections lead to the patient's death or to permanent injury, but in 8 cases (1.6 per cent.) there were complications necessitating rest in bed. Among these cases there were 2 of pulmonary infarcts in direct association with the treatment. This accident was due to faulty technique; both patients suffered from enormous varicosities and were in a hurry to have the treatment completed. The author states that the dosage of as much as 20 to 25 c.cm. at a single injection must in these cases be considered as a mistake and as being responsible for this complication. In 2 other cases there were signs of infarcts with phlebitis, in 3 cases phlegmons developed as a sequel to necroses, and in one case there was a severe haemorrhage. Meisen concludes that by skilled and cautious technique—as for example, by keeping the quantity of each injection within the 10 c.cm. limit—the frequency and seriousness of complications can be reduced, and that, compared with operative treatment, injections possess the advantages of being less dangerous and more likely to give permanent results, notably as far as subsequent ulceration and eczema are concerned.

287. Stovarsol in Syphilis.

F. W. CREGOR and F. M. GASTINEAU (*Arch. Derm. and Syph.*, January, 1927, p. 43) remark that the present method of intravenous arsenical therapy is not entirely satisfactory in all cases of syphilis. They sketch the history of the evolution of the therapeutics of [illegible] mpounds and show that so great was the [illegible], discovery of arsphenamine that it has [illegible]t in arsenic products, and caused emphasis to be placed on the trivalent arsenic. French workers have recently been using stovarsol, and Oppenheim of Vienna has obtained good results with it. Stovarsol can be given by the mouth, and it is well tolerated. The present authors have tried stovarsol for six months, giving as a general rule one 0.25 gram tablet per kilo of weight. A dose of about 0.5 or 1 gram was given in water before breakfast, some patients reaching daily doses of 2.25 grams for four days without untoward results. The course lasted from five to six weeks, a total of 15 grams being administered. A short rest period followed, Wassermann tests were performed, and succeeding courses were given similarly to the first. An account is given of fifteen cases so treated, and the results, compared with those of other observers, seem to indicate that stovarsol is useful in controlling the clinical manifestations of syphilis and causing good serological effects. Systemic reactions are slight as compared with those of the intravenous method, but the authors agree that the accurate dosage has yet to be determined. Tolerance appears to be high in comparison with other arsenicals.

288. Chinosol in the Treatment of Epidermomycoses.

LORTAT-JACOB and C. BIDAULT (*Presse Méd.*, January 12th, 1927, p. 49) recommend chinosol, the sulphate of ortho-oxyquinoline, in the treatment of certain diseases due to fungi. It is a yellow crystalline powder, easily soluble in water, slightly so in alcohol, and insoluble in ether. It does not coagulate albumin nor injure the skin, mucous membrane, or muscular tissue, though in some patients it may cause a slight and transient burning sensation when applied to mucous membranes in a strength of 1 in 2,000. Experiments have proved it to be non-toxic, and in America it has been orally administered in 15-grain doses without any ill effects. It inhibits the growth of m[illegible] staphylococci, *B. anthracis*, and avian [illegible] of 1 in 180,000 to 1 in 400,000. The [illegible] also that the growth of various tricophyta, microspora, the *Achorion schonleini*, and the *Epidermophyton inguinale* was inhibited by a 1 in 25,000 solution. The results of these experiments led to clinical trial, and chinosol has been used with beneficial effects in many mycoses; within a week tricophytic conditions of the face, arms, and wrists were cured by applications of a solution repeated many times daily. It is claimed that chinosol is a valuable dermatological remedy.

289. Digitalis and Calcium in Cardiac Failure.

C. C. DIMITRIU (*Bull. et Mém. Soc. Méd. des Hôp. de Bucarest*, October, 1926, p. 252) has found calcium salts of great value when combined with, or given alternately with, other cardiac tonics which were inactive when prescribed alone. He describes the case of a man, aged 51, with chronic bronchitis, emphysema, and effort dyspnoea. In 1924 an attack of cardiac failure was relieved by digitalis, ouabain, and diuretics, and subsequent slight attacks were easily relieved by digitalis. A severe attack of heart failure occurred in 1926, accompanied by cyanosis, orthopnoea, cough, precordial oppression, anasarca ascites, and obvious cardiac dilatation, the blood pressure having a maximum of 180 mm. Hg and a minimum of 110 mm. Only slight improvement followed the administration of Nativelle's digitaline and theosalvose

with bleeding and purgation. Ouabain caused a violent rigor, with hyperpyrexia, vomiting, and headache, and was discontinued, the patient's general condition remaining very bad. Wet-cupping over the liver and drastic purgation, followed by 50 drops of digitaline and 10 grams of calcium chloride daily for three days, produced free diuresis for five days, and afterwards the urine amounted to 1,500 to 1,200 c.cm. daily. Anasarca disappeared and the ascites was much reduced. The cardiac dullness diminished, and the pulse rate fell from 130 to 88. The maximum blood pressure fell 70 mm., and cyanosis, orthopnoea, and the hypostatic pulmonary congestion disappeared. For four days the calcium chloride treatment was continued, then for six days no medicine was given, but on the sixth day slight dyspnoea with tachycardia appeared. For two days 50 drops of digitaline and 20 grams of calcium chloride were given daily, then 2 grams of theosalvan for six days. This treatment again produced diuresis and relieved tachycardia and dyspnoea. All other symptoms disappeared, and the patient returned to work. Dimitriu claims that while neither digitaline nor calcium when prescribed separately is efficacious, their combination has an immediate and powerful effect in cases of severe cardiac dilatation. He thinks that calcium represents the true cardio-tonic element, while digitalis is only the agent which sensitizes the heart to the action of calcium. There may be danger of calcium producing emboli by reason of clots forming in the right side of the dilated heart, but Dimitriu considers that in desperate cases this risk must be taken. It is necessary to give large doses of digitalis to produce the result.

Laryngology and Otology.

290. Inhalation Therapy in Oto-laryngology.

C. SIMEONI (*Arch. Ital. di Otol.*, December, 1926, p. 653) describes tuberculosis as a general disease—a bacteriaemia—which only attacks the lungs in the third or ultimate stage, and may attack bones and glands previously. The subcutaneous method of introducing therapeutic substances is slow and very uncertain, and the intravenous is quicker and more certain in its action, but very inconvenient. Simeoni considers the peroral method better than either of these, and in diseases of the upper air passages the substances can be brought direct to the diseased area by inhalation. Certain salts, such as those of calcium, are not at all easily soluble or digested in the alimentary canal, and it has also been shown that these salts, administered hypodermically, are not absorbed and tend to form abscesses. The demineralization, and particularly the decalcification, of the tissues in tuberculosis is well known. The administration of calcium can take the form either of a dry cloud or a strong aqueous solution of the salt at 16°. The local changes on inhalation consist of irritation and congestion with expectoration of a considerable quantity of sputum. Some of the salt is absorbed and helps to reduce the decalcification. In treating lesions of the larynx it has been found that the infiltrative type responds best to the inhalation method and that the dysphagia associated with the ulcerative type is improved by the treatment, but the ulceration does not respond very well. The solution of calcium salts recommended consists of six parts of calcium lactate, five of calcium hypophosphite, and four of manganese lactate in one hundred of water. Usually about forty inhalations are given. The results of this treatment are that the laryngeal condition is greatly improved, the general health becomes better, and the pulmonary symptoms are lessened.

291. The Thymus Gland.

W. W. WASSON (*Arch. of Oto-Laryngol.*, December, 1926, p. 495) has investigated the thymus by *x*-raying the chests of young children during life and after death. In certain cases he was able to *x*-ray them shortly before death. After death he made various experiments, including the artificial inflation of the lungs, outlining the heart and thymus by opaque substances such as copper wire and lead foil, and in some cases injecting the large vessels with an opaque substance. He states that the heart shadow is formed by the heart and the superior and inferior venae cavae, and is surmounted by a triangular shadow formed by the great vessels and interrupted by the light area of the trachea. The shadow of the thymus is also triangular, and if present in any size it overlaps the shadow of the vessels. The base of the shadow overlaps that of the auricular part of the heart. The widest part of the thymic shadow is at the third interspace, and may be two to three times the width of the vertebral shadow at this level. If the shadow of the thymus does not overlap that of the great vessels it is a small thymus. The thymus lies between the sternum and the spine and can only expand in a lateral direction, and that at the expense of the lung room. By increasing the intrapulmonary pressure the thymus can be compressed between the sternum and the packet of vessels and the trachea, thus increasing the pressure on these structures. The author has found that in a large number of children there was a small thymus at birth, but that it grew steadily up to the age of 10 to 14 months and then receded gradually to the age of 28 to 32 months, when the shadow of the thymus was not apparent in the skiagram of the chest. He considers that the thymus is of maximum size at about 12 months, and that it shrinks to a small gland by about 2½ years. He describes a small gland as one which casts no shadow outside that of the great vessels. A moderate-sized gland throws a shadow twice the size of that of the upper dorsal spine, and a large one at least three times the size. In a large series he found that the underweight child had a small thymus and the overweight child had a large thymus. Wasson thinks that all children of more than normal weight should be *x*-rayed before an operation, and that operating on children over 2 years of age who have a large thymus is distinctly dangerous. *Irradiation* is used to reduce the size of a large thymus in a child under 2 years before a surgical operation and in all children over 2½ who retain enlargement of the thymus.

292. A Conservative Method of Treating Otorrhoea.

BIRKHOLZ (*Med. Klinik*, January 21st, 1927, p. 87) agrees with most authorities that conservative treatment is preferable in most chronic cases of otorrhoea. He considers that the cause of chronicity in many refractory cases in otherwise healthy children lies in a pathological condition of the Eustachian tube and of the mucous membrane surrounding its tympanic end, associated with excessive secretion. He regards the following points as diagnostic: (1) The perforation in these cases is frequently small and situated in the lower anterior quadrant; (2) the rest of the drum is little affected; (3) the secretion is typically tough, mucinous or seromucinous, and small in amount, while pus is usually absent; (4) if a Eustachian catheter is passed in these cases inflation is difficult, which indicates probable swelling of the mucous membrane lining the tube. Astringent treatment of the tube should therefore be instituted in all cases which, despite good general condition and a healthy naso-pharynx, resist the usual methods of treatment. The author has for some years used with great success a modification of a method suggested by Schwartze in 1868, which is as easily applied in children as in adults. The auditory meatus is washed out and dried, and the patient is politzerized if possible. While the head is bent so that the Eustachian tube is vertical not more than 5 drops of a 5 per cent. silver nitrate solution are instilled. This is sucked through the Eustachian tube by Toynbee's method, the patient swallowing while the nostrils are closed. If the tube is blocked to such an extent that this is ineffective an "external air douche" is applied by inserting the nozzle of a Politzer bag into the external auditory meatus and blowing air through while the Eustachian tube is kept vertical. When the solution passes down the tube slight burning is felt in the throat and one or two drops of the solution run out of the nostrils. The external meatus is then dried, no saline irrigation being necessary. The pathological condition clears up after two or three repetitions of this treatment. Large perforations and those situated in the upper posterior quadrant absolutely contraindicate the method.

293. Latent Cerebral Abscess following Mastoiditis.

G. COULET (*Arch. Internat. de Laryngol.*, January, 1927, p. 38) reports the case of a boy, aged 10, who had an acute mastoiditis for which a cortical mastoid operation was performed. As the cavity did not heal a radical mastoid operation followed, and the cavity became completely dry. The dura mater of the middle fossa was exposed but appeared healthy. Three years after the acute mastoiditis the boy was brought into hospital in a state of semi-coma, from which he could be roused just enough to obey instructions as to movements of eyes and limbs. He suffered from complete aphasia. He had been perfectly well during the three years, had regularly attended school, and had gained a good place in an average form. On the morning of his admission to hospital he had complained of a severe headache and had become rapidly comatose. The mastoid cavity was filled by bulging dura mater, which was punctured, and greyish purulent fluid, followed by normal cerebro-spinal fluid, was evacuated. The same night the temperature rose and the boy became completely comatose. The dura mater was at once opened and the cerebral abscess discovered and drained. The boy was very much better and the power of speech returned. It was obvious that a very old-standing cerebral abscess had burst into the subdural space and caused the sudden onset of symptoms. Meningitis supervened and death occurred in three days. The interesting features of the case are the latency of the abscess in the brain for two and a half years

with spontaneous rupture into the intrameningeal space, and the fact that, though the abscess was on the right side, aphasia—indicating a left-sided lesion—was present. The author raises the question whether he should have explored the meninges at the time of the earlier operations, but concludes that without some definite indication of intracranial lesion the meninges should not be punctured.

294. Unrecognized Nasal Sinusitis.

I. W. VOORHEES (*Med. Journ. and Record*, December 15th, 1926, p. 741) suggests that unrecognized chronic nasal sinusitis may be a source of general bacterial invasion of even more importance than tooth infection, and that the nose may well precede and supersede the teeth or the tonsils in the search for bacterial foci. While many cases of acute sinusitis subside spontaneously or after simple treatment, it is important to recognize the subacute, latent, or chronic infections of the paranasal cavities. Symptomatic of involvement of the frontal sinuses are headache occurring at a definite hour each morning and ceasing about the same time each afternoon, post-nasal discharge, and tenderness at the inner canthus and on percussion over the frontal bones. Since chronic purulent sinusitis may set up chronic tonsillitis, such tonsils should be removed before any sinus operation is attempted, as an acute tonsillitis not infrequently supervenes upon any intranasal operation. There may also be some associated nasal obstruction. Voorhees believes that many cases, though easy to diagnose, are often missed, but a definite diagnosis can be made from the history, careful clinical examination, irrigation and aspiration, and radiography. While the acute condition usually clears up easily, operation and prolonged treatment are required when it has become chronic.

Obstetrics and Gynaecology.

295. Treatment of Placenta Praevia.

G. L. BRODHEAD and E. G. LANGROCK (*Surg., Gynecol. and Obstet.*, January, 1927, p. 39) report a series of 165 cases of placenta praevia with eighteen deaths, and discuss its treatment. They advise that when this condition is suspected a firm tampon should be prepared before digital examination is made, so that any resultant profuse haemorrhage may be checked while arrangements are completed for delivery. Six of the eighteen fatal cases were patients in poor condition through loss of blood, the cervix being dilated to the breadth of two or three fingers, and it is suggested that Caesarean section might have saved their lives. This operation occupies less time than completing the dilatation of the cervix and performing version and extraction; the loss of blood is also little as a rule. Of twenty-two cases of central placenta praevia in women pregnant between six and eight months, three were successfully treated by Caesarean section and nineteen were treated by version, with four deaths. The authors add that after any method of delivery the uterus and vagina should be tightly packed with iodoform gauze as a routine procedure to control any active bleeding and to prevent subsequent haemorrhage. In view of the value of blood transfusion in these cases, preliminary typing of the blood is advisable in order that transfusion may be performed, if required, without delay.

296. Vicarious Menstruation.

D. C. ELKIN (*Amer. Journ. Obstet. and Gynecol.*, January, 1927, p. 65) reports a case of vicarious (supplementary) menstruation occurring in a single woman, aged 35. Menstruation, which began at the age of 12, had been regular, but was almost always accompanied by bleeding from some other organ, coincident with the periods and never in the intervals. In the earlier years this occurred from one or both nipples without any swelling or ecchymosis in the breast, and on several occasions there was haemorrhage from the gums and cheeks and into the root cavities of the upper incisors, causing severe toothache and necessitating extraction. From fifteen to twenty pulmonary haemorrhages occurred with negative physical signs, and there was bleeding at times from the stomach and bowels; on one occasion there were pin-point haemorrhages from the skin. The most unusual feature was brisk bleeding from the left eye, the blood overflowing the lids and running down the cheek in a steady stream. No bleeding point could ever be found and there was no conjunctival injection. On two occasions the haemorrhage was stopped by instilling three drops of adrenaline solution, 1 in 10,000, into the eye. At the age of 23 the appendix and right tube and ovary were removed without relief, and at 34 uterine suspension was performed, and the gall bladder, containing a stone, was removed, but without any subsequent improvement. The patient was admitted to hospital on account of severe abdominal pain following peritonitis; at the operation dense adhesions were found and a tense left tubo-ovarian abscess was removed, since when there has been no bleeding from any organ. Elkin concludes that the condition was a menstrual phenomenon due to ovarian dysfunction as proved by cure following oöphorectomy.

297. The Lumen of the Fallopian Tube.

W. ZORN (*Zentralbl. f. Gynäk.*, November 27th, 1926, p. 3054) has made careful measurements of the lumen of 84 freshly extirpated Fallopian tubes, using specially calibrated probes. He finds that the average width of the lumen in normal tubes of patients in full sexual activity, of gravid tubes, and of the tubes in chronic inflammatory conditions is 0.8 to 1.0 mm. A tubal lumen of 0.6 mm. diameter or less points with certainty to atrophy or hypoplasia of the oviduct. A lumen of 0.7 mm. denotes a borderline condition, and is chiefly found in patients at or near the menopause.

298. Spinal Anaesthesia in Labour.

S. E. RISACHER and R. WAITZ (*Bull. Soc. d'Obstét. et de Gynécol. de Paris*, January, 1927, p. 41) find that, if a strongly hypertonic solution of novocain is injected into the subarachnoid space of a seated individual, the drug, owing to its density, falls to the bottom of the cul-de-sac, and paralyses only the roots of the cauda equina, one drop of the solution being sufficient to produce an anaesthesia limited to the vagino-perineo-anal region. For use in obstetrical conditions the solution is prepared by dissolving 50 grams of novocain in 50 grams of distilled water; sterilization at 120° C. does not alter its anaesthetic properties. With a specially marked hypodermic syringe one drop of this solution is injected, while the patient is in a sitting posture; this is the equivalent of about three centigrams of novocain. Anaesthesia appears rapidly, being complete in five minutes, and lasts from one and a half to two hours. The muscular relaxation of the vagina, perineum, and anus is said to be absolute, and; while the pains are no longer felt, uterine contractions persist unaffected. After delivery uterine contraction is perfectly normal. No ill effects have resulted from the injection, only a slight headache being occasionally felt. The authors have used this method with great benefit in forceps applications; internal versions, embryotomies, breech presentations, and perineorrhaphies, but advocate its employment only in those cases in which labour has to be ended artificially.

299. Influence of Rectal Disease on the Female Genito-urinary Organs.

C. J. DRUECK (*Med. Journ. and Record*, February 2nd, 1927, p. 157) calls attention to the frequent association of diseases of the rectum and of the female pelvic genito-urinary organs. Anal fissure or the operation for haemorrhoids may cause either acute retention of urine or frequent micturition. Retroposition of the uterus may lead to obstructive constipation. A given causative factor may produce very different symptoms—for instance, one patient with an ovarian tumour had chronic constipation, while another had irregular bleedings after bowel evacuation. Carcinoma of the cervix and of the vagina may invade the rectum and cause fistulous openings, but only when in an advanced stage. On the other hand, low cancer of the rectum involves the vaginal wall comparatively early. The loose pelvic cellular tissue permits of easy dissemination of infection, which may result in a localized pelvic cellulitis or go on to general peritonitis. Ulceration within the rectum or trauma of its wall is the most frequent cause of pelvic cellulitis, while its chief symptom is pelvic and rectal pain, usually more accentuated on one side than the other. Symptoms of mastitis, ovaritis, and cystitis may appear. Ulceration of the rectum, and even constipation, may cause irregularity or suppression of the menses. Menstruation may be accompanied by diarrhoea or constipation. An ulcer of the rectum, anal fissure, or stricture will cause local neuralgia or even spasmodic dysmenorrhoea. On the other hand, rectal pain and tenesmus may be due to cystitis, vulvo-vaginitis, displacements, or adhesions of the uterus or appendages.

300. Low Transverse Arrest of the Foetal Head.

C. COGHLAN (*Med. Journ. of Australia*, January 8th, 1927 p. 52) draws attention to the not infrequent occurrence in an occipito-posterior position of the arrest of the advancing foetal head at the transverse diameter of the pelvis. He thinks that the fundamental cause of this condition is insufficient flexion of the head when engaged, so that the occiput and sinciput are nearly at the same level, the occiput slightly leading. When the head reaches the pelvic floor it is stopped and the occiput tends to rotate to the front, but, owing to its advance being resisted, extension is increased with each pain, so that the sinciput becomes level with the occiput and rotation ceases, equal forces acting now at opposite ends of the long axis of the head. With continued uterine action

the head is tightly jammed into the narrowing transverse diameter of the pelvis, and, in consequence of uterine retraction, cannot be displaced except perhaps under deep anaesthesia. In a case which Coghlan quotes in illustration, Kielland's forceps were applied with the blades in the occipito-mental diameter; upward displacement, flexion, and traction resulted in rapid rotation of the head and delivery of a stillborn child. The puerperium was uneventful, except for temporary incontinence of urine and faeces. The author recommends that in such cases, if Kielland's forceps are not available, the ordinary pelvic curved forceps should be applied biparietally to the foetal head in the occipito-mental diameter, with the outside of the pelvic curve towards the occiput. When flexion and partial rotation to the front have been obtained, the forceps should be removed and reapplied in the usual manner, with the inside of the pelvic curve towards the occiput. Coghlan adds that if the condition is recognized early, it is sometimes possible to displace, flex, and rotate the head manually under deep anaesthesia.

Pathology.

301. Vicarious Excretion in Nephritis.

ACCORDING to E. T. MCENERY, J. MEYER, and A. C. IVY (*Journ. Lab. and Clin. Med.*, January, 1927, p. 362) it is well known to clinicians that gastro-intestinal symptoms occur in the course of nephritis; these complications have been attributed to various factors, such as oedema of the gastric mucosa and involvement of the central nervous system. Van Noorden suggested that toxins probably played the more important part, and numerous observers have noted that substances usually excreted by the kidney may also be eliminated by the alimentary tract; ammonia, for instance, occurs in quantity in the stools of uraemic diarrhoea cases. The authors' method of investigation was to study the changes that occur in the secretion of gastric juice in nephritis. Pavlov pouches were produced in dogs and nephritis was caused by occluding the renal blood vessels for varying periods of time. It was found that acute nephritis resulting from occlusion of the renal vessels for forty-five minutes decreased but did not abolish the response of the meal, and that the chronic nephritis following such occlusion did not appreciably affect gastric secretion. In normal dogs 2 to 10 mg. per 100 c.cm. of urea was found in the secretion. When urea was given intravenously its amount in the gastric juice was also increased. Similarly an increase in the blood urea was noted in animals in which an experimental nephritis had been produced. In patients suffering from nephritis the authors found urea in the saliva and bile-free gastric juice, the quantity present being considerable in cases with a high blood urea content. The authors conclude, therefore, that the stomach as well as other portions of the gastro-intestinal tract must be considered to be organs of elimination in cases of nephritis and anuria.

302. Staphylococcal Erysipelas.

F. LÜLSDORF (*Münch. med. Woch.*, December 24th, 1926, p. 2211) states that although Fehleisen in the early eighties of the last century isolated a streptococcus which he regarded as the only causal agent of erysipelas, subsequent investigations showed that this view was not correct. In 1901 Jordan reported two cases in which undoubted staphylococci gave rise to erysipelas as well as to suppurative osteomyelitis and abscesses. According to Lexer there are no fundamental differences in the action of streptococci and staphylococci, as both may produce various degrees of inflammation. The occurrence of erysipelas in one case, of septicaemia in another, and of metastasis in a third, depends, according to Jochmann, on the local and general predisposition as well as on the virulence of the cocci. Experimentally, typical erysipelas has been produced by Jordan, Felsenthal, and Petruschky with staphylococci, by Neufeld with pneumococci, by Petruschky with *B. coli*, and by Rheiner with typhoid bacilli. Kulenkampff regards the following features as typical of staphylococcal erysipelas: (1) The peculiar bluish colour of the skin, which later assumes a dark blue hue. (2) The presence of dark cords resembling strings of pearls in the affected areas, and later small bullae. (3) A low tension and often relatively full pulse at the onset. (4) The euphoria of many of the patients. (5) The occurrence of miliary phlegmons in the terminal stage. (6) Staphylococcal septicaemia ends the scene. The disease lasts from five to twenty-four days, the average time being thirteen days. The morbid anatomy consists of an inflammatory process in the skin and subcutaneous tissue, lymphangitis and phlebitis or thrombophlebitis. In well developed cases the prognosis is unfavourable. Lülsdorf's case occurred in a wharfinger, aged 48, in whom the condition of the left arm was at first mistaken for anthrax. Recovery followed, the favourable issue being attributed to the fact that only one extremity was involved.

303. A Streptococcus in Rheumatic Fever.

J. C. SMALL (*Amer. Journ. Med. Sci.*, January, 1927, p. 101) states that the belief that rheumatic fever is an infectious disease has much in its support. The association of the onset of the disease with attacks of acute streptococcal tonsillitis, and the presence of these organisms in the valvular vegetations of ulcerative endocarditis of rheumatic origin have led to the theory that a particular group of streptococci is the etiological factor in rheumatic fever. Working along these lines Small isolated from the blood of a patient with acute rheumatism a streptococcus, for which he suggests the name *Streptococcus cardio-arthriditis*. Agglutination with the patient's serum occurred in dilutions up to 1 in 320. In rabbits acute arthritis and proliferative osteo-arthritis were produced by the organism comparable with the human type. The organism is described as a spherical, non-haemolytic, Gram-positive coccus of short chain formation. It stains readily, is non-motile and facultatively anaerobic, and possesses neither flagella, spores, nor capsules. The optimum temperature of growth is 37° C., and the organism is killed in six to ten minutes at 60° C.; enriched media are required. The organism is insoluble in bile, and ferments glucose, sucrose, inulin, raffinose, and salicin, with formation of acid but not gas. Mannitol is not fermented, and lactose by only some strains. Characteristic opaque, red-brown colonies are formed on blood agar. Vaccines of this organism have been beneficial in only a limited number of arthritic cases, but the administration of a serum, prepared first in the rabbit and then in the horse, resulted in marked improvement in the pain, tenderness, articular swelling, and stiffness. Small considers that the striking results obtained in cases of rheumatic fever by the administration of the serum in proper dosage warrants this preliminary report.

304. Persistence of Infectivity of Convalescent Scarlet Fever Patients.

EDITH E. NICHOLLS (*Amer. Journ. of Hygiene*, January, 1927, p. 84) has examined a series of forty patients suffering from scarlet fever in order to determine how long the *Streptococcus scarlatinae* remains in the throat during convalescence. Weekly cultures were made from the throat on blood agar plates. One colony was transferred to phosphate broth, which was incubated for four days, and filtered through a Berkefeld candle. The filtrate was tested for toxicity by intracutaneous injection of 0.1 c.cm. of a 1 in 1,000 dilution into Dick-positive and Dick-negative persons. Tests of the specificity of the toxin were made by mixing one portion suitably diluted with a human scarlet fever blanching serum and another portion with a non-blanching serum. Each mixture was then injected intracutaneously into a person with a positive Dick test. If a local erythema was present twenty-four hours later over the site where the toxin and non-blanching serum were injected it was concluded that the toxin was specific. In all the forty cases studied the *Streptococcus scarlatinae* was found in the throat cultures at the end of the third week, and the strains isolated produced fully potent toxins. Only a few patients were examined during the fourth and fifth weeks and none at a later date, so that it was not ascertained how long the specific organism remains in the throat. The author concludes, however, that patients convalescent from scarlet fever are still infectious three weeks after the onset, and recommends that isolation should be prolonged beyond the three-week period customary in Connecticut.

305. Renal Pelvic Duplication.

L. E. GRAJEWSKI and P. EISEN (*Urol. and Cut. Rev.*, January, 1927, p. 46) record five cases of this kind, one of which was bilateral and the others unilateral. In none of the cases were there more than two ureteral openings into the bladder. In only one instance were signs of disease present. Although in this case the duplication was bilateral, the pathological findings were confined to one side and consisted in a dilated ureter beyond a point of obstruction to the inserted catheter. The patient had extensive tuberculous peritonitis with ascites and visceral displacement with fixation, and pressure from without may have caused this obstruction with consequent dilatation. In all the other cases both pelves and ureters were of normal size. The variation in number and displacement of the calyces was about the same as is found in many otherwise normal kidneys. One case occurred in a female and four in males. The ages ranged from 19 to 36. None of the symptoms for which the patients sought relief indicated the existence of the renal anomaly. Complaints of weakness and lassitude were frequent and sometimes of backache and loss of weight. None showed any spinal anomalies or evidence of spina bifida occulta. The diagnosis of renal pelvic duplication can only be made by a pyelogram.

EPITOME OF CURRENT MEDICAL LITERATURE.

Medicine.

306. Thyroid Failure.

C. H. LAWRENCE (*Boston Med. and Surg. Journ.*, January 13th, 1927, p. 43) discusses the physiological background for the symptoms of thyroid failure and the results of treatment. Forty cases showing symptoms and metabolic derangements characteristic of thyroid failure were studied with a view to determining what functional disturbances were associated with various symptoms, and the results of the analysis were separated into two groups according to the presence or absence of myxoedema in order to determine the similarities and contrasts between them. Fatigue, palpitation, headache, vertigo, abnormal weight, deafness, irregular catamenia, and sterility showed no significant differences between the myxoedemic and the non-myxoedemic group; while loss of memory, dyspnoea, overweight, and sensitiveness to cold were more frequent in the former, and underweight and delayed puberty in the latter. In both groups interference with the basal metabolic rate, the circulatory efficiency, and renal function formed the basis of many symptoms of thyroid failure. It is stated that the presence of myxoedema is not essential to the existence of marked thyroid failure, its presence being apparently as much dependent on vascular pathology as on diminished thyroid function *per se*. In the absence of demonstrable organic disease depression of thyroid activity may be the cause of abnormal fatigue of the body as a whole, or of subnormal function of any of its parts. Lawrence adds that such depression of thyroid activity can only be determined in most cases by vital function tests, of which the basal metabolism is only one, and that the administration of thyroid extract is not often justified without the evidence afforded by such tests. The degree of response of symptoms to treatment depends largely upon the presence or absence of organic changes associated with the hypothyroidism, and thyroid extract can only render normal the function of organs structurally capable of normal function; it cannot remedy irreparable tissue changes even though of thyrogenic origin.

307. The Prognosis of Miliary Tuberculosis.

M. DE BRUIN (*Nederl. Tijdschr. v. Geneesk.*, December 4th, 1926, p. 2526) has collected 47 cases from the literature which were regarded as examples of recovery from miliary tuberculosis, and divides them into the following three groups: (1) Thirty cases in which it was very improbable that the disease in question really was miliary tuberculosis; (2) nine cases in which recovery followed haematogenous miliary tuberculosis; (3) eight doubtful cases. Some of the cases in the first group were published between 1850 and 1874, when the term "miliary tuberculosis" had not the same meaning that it has now. Wünderlich, for example, regarded acute melancholia, delirium tremens, and puerperal mania, among other conditions, as definite forms of miliary tuberculosis. To the same group belong the cases described by Burnard and Sayé, who diagnosed miliary tuberculosis from the appearance in the lungs of numerous small foci on *x*-ray examination. In three of the cases of the second group, reported respectively by von Muralt, Assmann, and Kern and Johan, the diagnosis of miliary tuberculosis was confirmed by a *post-mortem* examination at a later period. In Cohn's case, in which splenectomy was performed for supposed Banti's disease, pathological examination showed that the real condition was miliary tuberculosis, and complete recovery followed. In the other cases the diagnosis was made from the *x*-ray appearances in the lungs. As regards the ultimate prognosis De Bruin adds that it is remarkable that the three patients in whom the diagnosis of miliary tuberculosis was made on clinical grounds died some time later of tuberculosis. The recovery, therefore, was only temporary and not permanent. He thinks that the prognosis of miliary tuberculosis, though not necessarily hopeless, should be guarded, as there is always the possibility of the meninges and kidneys being affected after the tuberculous process has cleared up in the lungs.

308. The Blood Pressure in Pulmonary Tuberculosis.

As the result of observing 701 tuberculous patients over an average period of eight months, B. P. STIVELMAN (*Amer. Journ. Med. Sci.*, January, 1927, p. 46) comes to the following conclusions: Blood pressure determination is of little diagnostic value in incipient tuberculosis, since the arterial tension in patients with early disease falls within the normal limits. With the advance of the tuberculous process the blood pressure decreases to a greater extent in the active than in the more quiescent cases. The pressure is higher in fibroid disease than in other forms of tuberculosis, particularly in women over 40; this is probably secondary to the menopause. The incidence of haemoptysis is greater when the arterial tension is below the average for the condition, but the author thinks that the arterial tension and a haemoptysis are not etiologically related, but are coincidental symptoms of advancing disease. Haemoptysis in tuberculous patients with essential hypertension was less frequent than in cases with normal or subnormal blood pressure. The coexistence of pulmonary tuberculosis and syphilis produced a higher blood pressure and a more favourable immediate prognosis than in patients without syphilitic infection. The development of an effusion and the induction of pneumothorax had no appreciable and permanent effect on the blood pressure in the brachial artery, so long as the intrathoracic equilibrium was not unduly disturbed as the result of mediastinal displacement, which was prevented by early and judicious aspiration or careful adjustment of the intrapleural pressure. No indication of the course of the disease during treatment was given by changes in the blood pressure, but a higher arterial tension than the average for the age, sex, and degree of the disease or the patient rendered the prognosis more favourable.

309. Herpes Zoster Associated with Bismuth Treatment.

SÉZARY, PERNET, and GALLERAND (*Bull. Soc. Française de Dermatol. et de Syph.*, November, 1926, p. 654) report two cases of herpes zoster occurring in syphilitic patients under treatment by bismuth injections, and suggest that the eruption might have been due to the bismuth. A few similar cases have been recorded. In the present cases, although the eruptions were typical, they were not accompanied by any pain, disturbance in health, or subsequent scarring. Neither of the patients had been in contact with persons suffering from varicella, nor were there other cases of herpes. In one case the rash appeared during treatment, and in the other forty-eight days after the end of a course of bismuth. Another case of herpes possibly due to bismuth is reported by Martineau (ibid., p. 657).

310. Persistence of Streptococcus scarlatinae in Convalescent Scarlet Fever Patients.

E. E. NICHOLLS (*Amer. Journ. Hyg.*, January, 1927, p. 84) made an investigation of scarlet fever cases to determine how long toxin-producing scarlatinal streptococci persisted in the throat after recovery from the acute stage of the disease. For this purpose throat cultures were taken at the end of each week of the patients' stay in hospital in forty cases of scarlet fever. As the patients were admitted at an early stage these periods corresponded closely to the weeks of the disease. All types of cases were chosen—mild, moderate, and severe. Both sexes were represented, and the ages ranged from 2 to 48 years. Some were treated with antitoxin and some were not. In every case *Streptococcus scarlatinae* was found in the throat cultures at the end of the third week. There seemed to be little diminution in the degree of throat infection, as judged by the amount of growth, irrespective of the severity of the case, the use of antitoxin, or the presence of complications. Nicholls concludes that patients convalescent from scarlet fever are still infectious three weeks after the onset of the disease.

Surgery.

311. Pre-operative Preparation of the Diabetic Patient.

E. H. MASON (*Canadian Med. Assoc. Journ.*, January, 1927, p. 23) asserts that in properly handled diabetic cases the surgical mortality should be very little, if any, above that of the non-diabetic. In the preparation of the diabetic patient for operation attention should be paid to minor details in the daily hygiene, such as treatment of boils and pimples and cleanliness of the skin. The patient should not be dehydrated, the reserve glucose should not be exhausted by prolonged semi-starvation, and there should be no ketosis. An abundant intake of water (2,000 c.cm. daily) will prevent dehydration, and a diet containing at least 1 gram of carbohydrate per kilo of body weight, supplemented with insulin to ensure oxidation in part and storage of the remainder, will maintain a satisfactory glucose reserve and also abolish ketosis. Immediately before the operation an additional 10 units of

insulin should be given. For anaesthesia ether and chloroform should be avoided, and gas, gas and oxygen, or a local anaesthetic be used. Post-operative treatment is as important as the pre-operative. Freedom from glycosuria and ketosis should be maintained through diet, fluids, and insulin. Vomiting should be guarded against, and, if nausea persists, gastric lavage should be performed before vomiting starts. The diet should be gauged by the carbohydrate tolerance of the patient, fluids and soft foods being given at the start. Mason adds that the so-called diabetic gangrene occurs usually in untreated or poorly treated cases. Associated with the reduced carbohydrate tolerance and hyperglycaemia there is an arterial change, and the author asserts that the last is primary, the hyperglycaemia and glycosuria being secondary to arterial changes in the pancreas. Prophylactic treatment of diabetic gangrene is most important, and by a strict control of the diabetic state and daily attention to the local condition much can be accomplished. Mason has found that several cases of extensive gangrene have been completely healed by purely medical treatment, including the control of the condition, rest, warmth, daily exercises, and general and local exposures to ultra-violet light from a quartz mercury vapour lamp.

312. Congenital Pyloric Stenosis.

A. C. STRACHAUER (*Annals of Surgery*, January, 1927, p. 67) finds that in congenital hypertrophic pyloric stenosis the pyloric region is occupied by a tumour measuring about an inch in length and three-quarters of an inch in diameter. It consists of massive hypertrophy of the circular musculature of the pylorus. As a result the pyloric canal becomes stenosed and lengthened, interfering with the outlet from the stomach. The lesion has been seen in a 7-months' foetus and in the stillborn, and would seem to be developmental. It is often impossible to palpate the tumour in these cases as it may be covered by the liver, and *x* rays are not of much help in making a diagnosis. Before operating on such patients careful preparation is essential, gastric lavage and the administration of water being most important. The Rammstedt operation is the standard and safest procedure. The circular muscle is divided, and retracts and undergoes atrophy, thus relieving the obstruction. After division of the muscle a free portion of omentum is sutured over the incision. In a series of forty-eight cases reported by the author there was one death. Ether was the anaesthetic used; it appears to give the best and most satisfactory results. Local anaesthesia was unsatisfactory owing to straining of the infant, causing protrusion of the bowel through the wound and increased shock.

313. Angioma of the Tongue.

CHASTENET and GÉRY (*Bull. et. Mem. Soc. Nat. de Chir.*, January 22nd, 1927, p. 10) record an interesting and unusual tumour of the tongue. A woman, aged 19, had noticed its presence for a considerable period, but it had not grown appreciably in size. It caused no pain, but there was a little difficulty in speaking. The tumour was on the right side of the tongue, near the anterior margin, and was the size of a hazel nut. It was elastic and painless on palpation. The movements of the tongue were free and the overlying mucosa appeared normal. The tumour was removed with a local anaesthetic. It was nodular in appearance, like an adenoma, and on section was reddish and homogeneous to the naked eye. It consisted of fibrous tissue with cavities containing blood, and was considered to be a fibro-angioma. It was therefore probably of congenital origin and had undergone partial fibrosis in portions of the original angiomatous tissue.

314. Disease of the Sacro-iliac Joint.

A. LUX (*Wien. klin. Woch.*, January, 1927, p. 88) believes that sacro-iliac disease is far commoner than is supposed, and is often wrongly diagnosed as sciatica or lumbago. While primary tuberculosis of this joint does not, in his opinion, occur, chronic inflammatory changes are common, and, whether following chronic arthritic change or not, severe pain is often experienced following very slight trauma in this region; golf players, and persons accustomed to much stooping or carrying heavy weights, are instanced. The history is usually of sudden and severe, but not very clearly localized, pain in the lower part of the back, after some definite exertion. This improves slowly, but always recurs on movement of the upper part of the body, such as stooping or sitting. In examining the patient, Lux emphasizes the necessity for extreme gentleness, when, with the patient lying on his abdomen, a point of maximum tenderness may be made out over the joint, usually at the point of insertion, at the level of the fourth lumbar vertebra, of the posterior sacro-iliac ligament. Lasègue's sign is usually positive in these patients, and so is the attempt at compression of the iliac bones; but these signs are also present in severe sciatica, which must be distinguished by other methods. An *x*-ray examination is important to confirm the diagnosis and to eliminate the possibility of impacted stone in the kidney or ureter, or undue pressure on the sacral nerve plexus. In women retroversion of the uterus must be excluded. The treatment consists of massage and diathermy; rest, perfectly flat in bed, and on a hard mattress, is very important, and should be continued, even if it causes severe pain, for which the usual analgesics may be employed.

Therapeutics.

315. Thyroid Extract in Post-operative Embolism.

W. WALTERS (*Minnesota Med.*, January, 1927, p. 25) suggests reducing the incidence of post-operative embolism in elderly patients by the use of thyroid extract. With a view to increasing metabolism, with consequent increase in peristalsis and respiratory depth and acceleration of blood flow, and generally speeding up all the functions, 2 grains of thyroid extract were given by the mouth three times a day for seven days, commencing from the third or fourth day after operation and continuing until the patient was out of bed. Movements in bed and from side to side were recommended in order to increase the rate of circulation. Of 1,745 major operations thus treated no patient over 70 years of age died from pulmonary embolism and no deleterious effects were noted. The value of increased metabolism in the prevention of thrombosis and embolism is supported by Plummer's observation that these accidents rarely occur in severe cardiac decompensation coincident on hyperfunctioning thyroids. Experiments with the extracorporeal vascular loop in rabbits showed that thrombosis normally occurred in from four to ten minutes, whereas after administering 1 mg. of thyroxin daily for three days thrombosis did not occur for from twenty-five to thirty minutes, and this retardation was sustained for three days. Walters considers that there is reason to hope that post-operative embolism may be prevented by increasing metabolism in this way.

316. Treatment of Asthma by Ultra-violet Rays.

J. SAIDMAN (*Bull. Soc. de Thér.*, December 8th, 1926, p. 262) states that the first case of infantile asthma treated by ultra-violet rays was recorded by Mme Henry at the Société de Pédiatrie, although some writers had previously published cases in adults so treated. Saidman now records his observations on thirty-six asthmatic patients treated by ultra-violet rays whom he had kept under observation for a considerable time. All the patients had previously undergone a variety of anti-asthmatic treatment, including nasal sprays, administration of adrenaline, potassium iodide, glandular extracts, and climatotherapy, from which some had derived transient benefit. Although actinotherapy, like other measures, does not produce a permanent cure, and relapses occur in two-thirds of the cases, the number of the attacks is considerably reduced. Saidman groups his patients in the following four classes: (1) Children below 3 years of age. Out of five cases three were successes and two failures as regards the asthma, but in every case the rays had a good result on the general condition. (2) Children aged from 3 years up to puberty. Thirteen out of fourteen cases were successful, and in half the cases the attacks disappeared after the first application of the rays. (3) From puberty to 30 years of age. In this group the action of the rays was less rapid and more uncertain. (4) In adult life and old age. Although the results were incomplete, the cough became less frequent and distressing, the expectoration diminished, and the general condition improved under treatment.

317. Glucose and Insulin in Obstetric Toxaemia.

W. E. LEVY (*Amer. Journ. Obstet. and Gynecol.*, December, 1926, p. 866) states that the addition of insulin to the already successful glucose treatment in certain toxic conditions of pregnancy has proved remarkably beneficial. Thalhimer's work on post-operative acidosis with vomiting led to his investigating the pernicious vomiting of pregnancy, the basic idea being that the acidosis which is so prominent in the last stages of this vomiting is not only a result of the stomach's intolerance of food but also a factor in producing it. If the resulting vicious circle can be broken either by abortion, which removes the toxin of pregnancy, or by the correction of the acidosis, good results may be expected. If the vomiting, whether toxic or neurotic, is not checked a starvation acidosis will ensue. Levy has used the combination of glucose and insulin with marked success in the vomiting of pregnancy, in eclampsia and pre-eclamptic toxaemia, and in acidosis following haemorrhage. In the last-named condition, although acidosis is not necessarily present in shock, it often exists, may be extreme, and needs rapid treatment. It is important to distinguish between a true eclamptic

toxaemia and a purely renal condition, since in the latter glucose and insulin are valueless. Levy believes that this treatment would be beneficial in the acidosis of sepsis. His method of administration is to give 500 to 1,000 c.cm. of a 10 per cent. glucose solution with one unit of insulin to each 3 grams of glucose used, administering one-third of the amount of each until the whole has been given, and injecting the solution slowly. The glucose is given intravenously and the insulin hypodermically. Levy emphasizes that this therapy should be preceded by careful laboratory determinations and the dosage based on these findings. He controverts the conclusion of Stander and Duncan that the blood sugar is increased in eclampsia, and holds that their advice to use insulin without the necessary quota of glucose is most dangerous.

Radiology.

318. X-Ray Diagnosis of Pleural Effusions.

L. R. SANTE (*Journ. Amer. Med. Assoc.*, January, 1927, p. 215) considers *x*-ray examination most important in the detection of pleural effusions. Diagnosis of localized collections of fluid or of a generalized pleural effusion with underlying consolidation is always a matter of difficulty, and is sometimes impossible by ordinary physical examination. In general effusions the lung is well aerated and movement is free; there is a dense *x*-ray shadow in the lower part of the thorax, the costo-phrenic sinus being obliterated. The upper border of such an effusion is curved, concave, and extends upwards and outwards from the hilum to the axillary line, the shadow being little influenced by changes of position. Where the effusion is large the mediastinal contents are displaced, or, in the absence of such displacements, there is persistence of the aeration of the apex. At the diaphragm the liver and spleen shadows are continuous with the thoracic shadow. Where the lung is consolidated or fibrosed there is a ribbon-like shadow along the parietal wall of the chest. In local effusions, which usually appear during the course of an inflammatory process, the effusion generally occurs where two pleural surfaces come in contact. Whatever the site of the effusion, there is one particularly characteristic shadow which shows a convex rounded border with its base at the periphery and its convexity inwards towards the lung.

319. Radiotherapy for Cancer of the Tongue.

G. ZANOTTI (*Il Policlinico*, Sez. Chir., January 15th, 1927, p. 34) considers that a primary cancerous lesion confined to the tongue may be satisfactorily treated by deep radium therapy. If, however, the lesion is quite small and at the tip of the tongue, it is better, both for diagnostic and therapeutic reasons, to excise freely. Where necrosis has followed unsuitable radium treatment it is useless to continue it, and it is better to proceed surgically. Penetrating radiotherapy, either alone or associated with radium puncture, is said to be unable to cure cancer of the tongue, and still less the glandular metastasis; in advanced cancer, with palliative irradiation, it is useful. For enlarged and definitely cancerous glands external and deeply penetrating radium therapy is more effective than surgery. Zanotti adds that it should be remembered that a large percentage of the glands removed (40 per cent. according to Poirier) are *not* cancerous. Where the glands are bulky it is advisable to excise as much as possible as a preliminary to the radium treatment, but if the glandular enlargement is not marked radium therapy alone will suffice. Treatment by local radium puncture with external application should be simultaneous and continuous, using screened tubes of 2 mm. and 1 mm. platinum respectively. The dose should be weak, but capable of destroying cells in mitosis. If less screened tubes are used, it is better to divide the treatment into two stages, so as to avoid the risk of necrosis. Sterilization of the tumour by long-continued treatment according to the method of De Nabias is generally preferable. Since the radium treatment of lingual cancer is so full of technical difficulty it should be given in a properly equipped hospital.

320. Radium Treatment of Experimental Tar Cancer.

G. STOEL (*Nederl. Tijdschr. v. Geneesk.*, January 8th, 1927, p. 234) finds that experimental tar cancer in the mouse's skin can be caused to disappear entirely with almost the same dose as in the case of human cancer of the skin. Disappearance of the tumour is followed by a "radium sore," which also heals up in course of time. Complete healing of the tumour by this method is a strictly local phenomenon. No effect from irradiation on dissemination of the growth was observed in these experiments. Histologically the effects of irradiation were shown by the following appearances, which reached their fullest development in two to four days: (1) changes in the tumour cells, consisting in swelling of the nuclei, basophilia of the plasma, and the accumulation of large masses of nuclei; (2) disturbance of mitosis; (3) keratinization; (4) engorgement of the blood vessels. Subsequently the irradiated tumour cells are invaded by other cells, especially polymorphonuclear leucocytes, and later all kinds of connective tissue cells. The arteries in the irradiated area often show much thickening of their walls, whereby the lumen of the vessel is narrowed. After destruction of the tumour the space is occupied by newly formed connective tissue and fat.

321. Radiotherapy for Epithelioma of the Skin.

F. H. RIVERO (*Rev. med. Panamericana*, November, 1926, p. 23), who records several illustrative cases, describes three varieties of epithelioma of the skin—namely, spinocellular, basocellular, and naevocellular, with the appropriate treatment for each variety. His conclusions are as follows: Naevocellular epitheliomata should be treated by electrolysis exclusively. The basocellular forms may be treated by *x* rays, or, better still, by radium, which leaves soft and almost invisible scars. The spinocellular forms, which are refractory to deep radiotherapy in many cases, should be treated by the hard gamma rays of radium according to Regaud's technique. In districts where these methods of treatment are not available he recommends curetting away the tumour under local anaesthesia with novocain and adrenaline, and swabbing the curetted area with a solution of methylene blue (methylene blue 1 gram, glycerin and alcohol of each 5 grams).

322. Radiological Diagnosis of Ascariasis.

M. MUZII (*Il Policlinico*, Sez. Prat., January 17th, 1927, p. 83) publishes details of three cases of ascariasis, with radiograms showing the presence of the parasites. The medium used was a mixture of milk and water containing 150 grams of gelatinous barium sulphate. The worms appear as transparent streaks, and by pressing on the intestine to squeeze out the barium they can be shown more clearly. In some cases the worms swallowed some of the barium mixture and became opaque owing to the barium in their intestinal canal.

Obstetrics and Gynaecology.

323. Backache in Women.

F. KERMAUNER (*Wien. klin. Woch.*, January 6th, 1927, p. 15) protests against the commonly accepted teaching that backache in women is invariably due to the condition of the genital organs and that it is needless to look for any troubles other than uterine displacements. He reports the case of a patient who a year previously had had an *operation for correction* of uterine displacement. The anatomical result was excellent, but the sacral pain and dyspareunia were entirely unrelieved. The patient was thin, asthenic, and very depressed. Another patient was a bi-para, aged 33, who in the seventh month of her second pregnancy had severe pain radiating from the sacrum and buttocks to the legs. She had a normal confinement, but subsequently suffered from persistent sacral pain, which was aggravated on straining. She was thin and delicate, but the genital organs were normal. She had lordosis in the lumbar region with contraction of the *left erector spinae*, and pain on pressure over the fifth lumbar vertebra. Skiagrams showed an oblique fissure in the arch of the vertebra, indicating apparently spina bifida occulta; this had possibly been aggravated by changes in the bones and ligaments during pregnancy. The pain was relieved by irradiation over the site of the lesion. Another woman, aged 27, who had borne three children, had sacral pain towards the end of her first pregnancy, which improved after confinement but became worse in the subsequent pregnancies. A skiagram showed relaxation of the sacro-iliac ligaments with rotation of the sacrum on its transverse axis. A fourth patient had had a prolonged and difficult confinement due to the size of the child. Recovery was protracted, and a skiagram showed a lumbar lordosis. In these last two cases strong pelvic belts gave definite relief. The author believes that damage to the pelvic bones and ligaments due to pregnancy is much more frequent than has been supposed hitherto, especially when the normal temporary relaxation of the sacro-iliac ligaments persists. In some cases arthritic changes have been observed. Post-climacteric obesity, by increasing the size of the abdomen, may produce similar changes in the pelvic bones and joints.

324. Paratyphoid Ovarian Abscess.

R. CORDUA and E. A. KECK (*Zentralbl. f. Gynäk.*, October 23rd, 1926, p. 2747) refer to fourteen cases in which typhoid bacilli have been found in abscesses of the ovary. They record the case of a woman, aged 36, who in the fourth week of paratyphoid B fever suffered from acute abdominal pain; double

adnexal tumours which had been previously recognized became at the same time very tender, especially the left. At operation a large left inflammatory adnexal tumour was found adherent to the omentum and intestine; it burst, giving issue to foul pus from which *B. paratyphosus* B was isolated. *Inflammatory disease of the left adnexa had been noted four* years previously, so that the case is regarded as secondary infection by the paratyphoid bacillus of pre-existing inflammatory adnexal disease. Allusion is made also to the case of a woman, aged 32, from whom chronically inflamed and adherent right adnexa were removed at an operation for abdominal pain of four years' duration; the ovary contained a small abscess from which *B. paratyphosus* B was isolated. The history afforded no evidence of a pre-existing typhoid or paratyphoid illness, but the tumour was adherent to the sigmoid colon.

325. Labour with Double Uterus.

VAUDESCAL and KERNÉIS (*Bull. Soc. d'Obstét. et de Gynécol. de Paris*, December, 1926, p. 607) relate the case of a woman, aged 25, whose first four pregnancies terminated respectively in abortion in the fourth month, a difficult forceps delivery, and two spontaneous live births. Twin gestation was diagnosed during the ninth month of a fifth pregnancy; after delivery of the first infant at term the existence of double cervix and corpus uteri was recognized. The puerperium appeared normal, save that lactation was absent; the second foetus was not born until forty days later, with dystocia, attributed to obstruction by the empty half of the uterus or to an intrapelvic septum. The second child died, but in the second puerperium the breasts secreted so freely as to permit suckling of the first infant. J. BUREAU (ibid., p. 619) describes cases of premature expulsion and of retention of the decidua of the empty half of a double uterus of which the other side was pregnant. In the first case a woman, aged 25, became pregnant shortly after division of a vaginal septum for dyspareunia. During the eighth month she was admitted to hospital for abdominal pain, and there expelled the lining membrane of the non-pregnant uterine cornu; labour occurred normally one month later. The second patient, a primipara aged 23, was delivered, after section of a vaginal septum, of a live foetus presenting by the breech. When it was decided during the puerperium, on account of pyrexia and fetid lochia, to explore the uterine cavities, the one which had lately been gravid was found to be healthy and empty, and the other to contain a retained and infected decidua. Both these patients had amenorrhoea following conception.

Pathology.

326. Oral Sepsis and Focal Infection.

E. C. ROSENOW (*Med. Journ. of Australia*, November 27th, 1926, p. 735) states that clinical observation and experiments on animals have shown the importance of even small and symptomless localized infections as a frequent source of various systemic diseases. Many reports of the relief of symptoms following the removal of foci of infection have been published, and the author refers to his own work on gastric ulcer and arthritis, due to oral sepsis, and to that of others on the etiology of pyelonephritis, ulcerative cystitis, iritis and other eye diseases, ulcerative colitis, and endocervicitis, due, in many cases, to a streptococcus. Haden has even succeeded in producing onychia in rabbits with streptococci from infective foci in patients suffering from multiple onychia —an example of extreme specificity. There is a fundamental difference between an area of infection around a joint, as in chronic arthritis, and infection in the jaw around dead or diseased teeth, or *in the tonsils containing dilated crypts* with narrowed or plugged orifices, or an encapsulated abscess. In systemic or secondary foci the number of organisms is usually small, whereas in the primary foci mentioned the number is usually large. Clinical observations indicate that localized infections—as, for example, in the tonsils, teeth, and sinuses—are more likely to be associated with systemic effects than are those in other structures, such as the lung, or in the urinary tract. Generally speaking, the damage due to infective foci is directly proportional to the lack of drainage. The more virulent the bacteria the less they need a gross focus for entrance, and the lower their virulence the greater is the factor of focal infection in the production and maintenance of chronic disease. An infective focus which cannot heal or drain and teems with organisms, often in mixed culture, is recognized not only as a favourable starting point of invasion, but also as a suitable place for bacteria to maintain or acquire great virulence. Rosenow claims to have produced gastric ulcer in animals during a series of experiments on the transmutation of pneumococci and streptococci with laboratory strains which had attained increased virulence by repeated passage through animals. These results led to the formulation of the theory of elective localization. Experiments have indicated that the elective localizing power of bacteria in infective foci determines largely the site of the systemic lesion or disease, but this does not always occur independently of predisposing factors. Exposure, trauma, fatigue, and many other factors undoubtedly lower local or general resistance, and thus increase the probability of elective localization of bacteria and of other infective processes. Direct injection of bacteria grown in foci such as tonsillar crypts has often been followed by localization, with production of lesions corresponding to those of the patient. There are many difficulties in the practical application of the principles of focal infection and elective localization. Systemic diseases, once established, and often associated with anatomical changes, may continue after all evident foci have been removed, but instances of cure or of arrest of systemic disease by removal of infective foci show that this is indicated in almost every case in which focal origin can be proved.

327. The Virus of the Rous Sarcoma.

F. PENTIMALLI (*Lo Sperimentale*, January 25th, 1927, p. 623), repeating Gye's experiments on the virus of Rous sarcoma, paid particular attention to the inactivation of the virus by chloroform, and finds that if an extract of the tumour filtered through sand is treated with chloroform—1 c.cm. of chloroform being added to 10 c.cm. of filtrate—it is completely inactivated at 37° C. in three hours. But if only 0.1 c.cm. of chloroform is added the resultant mixture, when injected with kieselguhr, is often, though not always, able to produce a tumour in a dose of 5 c.cm. or occasionally of 2 c.cm. The chloroform was liberated from the mixture before injection by evaporation in a current of warm air. Having shown that 1 c.cm. of chloroform is sufficient to destroy the virus, he then tried to repeat Gye's work on the cultivation of the virus *in vitro*. He found that a mixture of 1 c.cm. of chloroform-treated filtrate (specific factor) *plus* 1 c.cm. of a fourth subculture of the virus in modified Hartley's broth with the addition of kieselguhr, when injected into the pectoral muscle of a hen, completely failed to produce a tumour. A few successful experiments resulted when only 0.1 c.cm. of chloroform was used to kill the virus, but in these cases the controls were also positive. Certain observations lead him to believe that the kieselguhr is not entirely inactive. He finds, for example, that it is possible to produce a tumour with a mixture of chloroform-treated filtrate (0.1 c.cm. of chloroform being used) and 1 c.cm. of Ringer's solution with kieselguhr more easily than when a mixture of chloroform-treated filtrate with 1 c.cm. of a culture of the virus is employed. He thinks, therefore, that the kieselguhr may act by rendering active a virus that has not been completely destroyed. Having failed to confirm Gye's results Pentimalli endeavoured to repeat Carrel's experiments on the production of tumours with a mixture of embryo pulp or inflammatory tissue and arsenious anhydride, indol, or scatol; these attempts also failed. He concludes that neither the virus nor the chemical theory of the nature of the Rous sarcoma is satisfactorily demonstrated.

328. The Cerebro-spinal Fluid in Human Rabies.

K. LÖWENBERG (*Münch. Med. Woch.*, December 24th, 1926, p. 2203) records his observations on the cerebro-spinal fluid in four cases of human rabies. In the first case, in which death occurred twenty-four hours after lumbar puncture, the spinal fluid was clear and under increased pressure, and the Nonne, Pandy, and gold-sol reactions were negative. The fluid, therefore, was apparently normal, although the disease ran a very severe course after an incubation period of about seven weeks, and the central nervous system showed several degenerative changes on histological examination. In the second case, in which paralyses of both lower extremities occurred five months after termination of prophylactic treatment, the Nonne, Pandy, and Weichbrodt tests were positive and the gold-sol test negative. In the third case, in which death occurred in the acute stage after an incubation period of six months, the cell count was not increased, although severe inflammatory symptoms were present in the mid-brain. In the fourth case, in which rabies developed fourteen days after the patient had been bitten on the mouth by a mad dog, lumbar puncture showed a turbid fluid due to well marked leucocytosis. The necropsy, which was performed three hours after death, showed well developed acute leptomeningitis and severe degenerative change in the cerebral cortex, cerebellum, and spinal cord. Löwenberg adds that these cases show that human rabies is one of those infections in which only slight changes are found in the cerebro-spinal fluid in spite of very severe lesions in the central nervous system.

EPITOME OF CURRENT MEDICAL LITERATURE.

Medicine.

329. Vaccination of Pregnant Women and Newborn Infants.

J. A. URNER (*Amer. Journ. Obstet. and Gynecol.*, January, 1927, p. 70) reviews the literature and reports the results of vaccination against small-pox of 129 pregnant women and 200 newborn infants. The period of pregnancy ranged from the twelfth to the thirty-ninth week; 66 women were vaccinated from the eighth to the tenth month and their infants reacted with 66 per cent. positive vaccinations. Between the first and eighth months 63 women were vaccinated, and their infants reacted with 71.5 per cent. positive vaccinations. Only 5 per cent. of the women successfully vaccinated showed rather severe symptoms of backache, anorexia, and malaise with a rise of temperature, and there was not a single case of threatened abortion, miscarriage, or premature labour. It was found that newborn infants stood vaccination well, and even better than older children; the temperature curves did not differ in any respect from those of unvaccinated infants, and no infant showed exanthemata or other generalized reactions. In no single instance could intrauterine transmission of immunity to small-pox or vaccination be demonstrated. Urner concludes that intrauterine transmission of immunity to small-pox should not be taken into account, as at best it is passive, slight, infrequent, and of insufficient consequence to protect the infant from either vaccination or small-pox.

330. The Serum Prophylaxis of Measles.

R. DEBRÉ, H. BONNET, and P. JOANNON (*Arch. méd., chir. et esp.*, January 29th, 1927, p. 156) state that four factors must be taken into account in considering the causes of failure of the prophylaxis of measles by the injection of convalescent serum—namely, the quality of the serum, the quantity administered, the state of health of the recipient, and the date of the injection. A "bad serum" may be totally destitute of immunisins or poor in protective antibodies. Deficiency of the serum in immunisins may be primary, or secondary to heating or to being kept too long. Failures, however, are much more frequently due to an inadequate dose. Although the dose in every case should be proportionate to the age of the individual, in many circumstances it must be increased to make up for the scarcity of immunisins in the serum. Thirdly, a serum with a normal quantity of anti-measles immunisins may show diminished efficiency because the organism, owing to the concurrent illness, is unable to make a proper use of them. Fourthly, when the serum is injected as late as the ninth or tenth day of incubation it is usually ineffective; the attack of measles is not attenuated and grave complications may occur. In some cases a good serum which has been kept only a few weeks and injected in sufficient doses at the right time into healthy subjects fails to afford any protection against measles. These failures, for which at present there is no explanation, do not exceed 1 per cent.

331. Diphtheria Carriers among School Children.

S. FEILBERG (*Tidsskrift for den Norske Laegeforening*, February 15th, 1927, p. 181) compares the incidence of diphtheria carriers in school children in Oslo during the periods 1903 and 1925–26. During the severe diphtheria epidemic in 1903 an examination of 967 school children in June showed that 9.2 per cent. were carriers. In September of the same year 4.2 per cent. of 4,455 school children were found to be carriers. During this year the incidence of clinical diphtheria in Oslo was 6.9 per 1,000. In the period 1925–26, when the incidence of clinical diphtheria was only between 0.2 and 0.3 per 1,000, an examination of 2,085 school children showed that only 0.45 per cent. were carriers. Though the diphtheria bacilli, which were all obtained in pure culture, conformed to the standard tests indicative of true diphtheria bacilli, they were avirulent to guinea-pigs, and in this connexion the author points out that there are no definite means of proving that the diphtheria bacilli of carriers are avirulent to man; virulence to guinea-pigs does not necessarily imply virulence to man. The upshot of the author's comparison of the one period with the other is the demonstration of a definite parallelism between the frequency of clinical diphtheria and that of carriers. The number of carriers would seem to be greatly in excess of the number of patients suffering from clinical diphtheria; this excess is somewhat reduced, but not altogether banished, during epidemics of the disease. The author admits that no clue is given as to whether the clinical cases should be regarded as primary and the carriers as secondary, or vice versa. All that can be claimed is that the striking parallelism demonstrated is an indication that there is some relation between the frequency of clinical cases and that of carriers. As in the observations of 1925–26 no case of clinical diphtheria developed in contact with any carrier, the author sees in this observation confirmation of the now general opinion that diphtheria carriers need not be isolated nor be the object of any special measures in the majority of cases.

332. Congenital Malaria.

F. MAGIOLI (*Thèse de Paris*, 1926, No. 188) states that though there are several cases on record of congenital malaria the condition is rare, as it has often been proved that transmission of the parasite by the mother to the child is not constant. The transmission may occur at all stages of pregnancy, and especially in the last three months. All forms of malaria are liable to be transmitted, but it is chiefly when infection has taken place in the second part of pregnancy and in badly treated cases that the parasite is most likely to pass through the placenta. The same parasite is found in the child as in the mother. The placenta is the centre of activity in which the young forms of the haematozoön are found in large quantities, whereas the umbilical and peripheral blood is poor in parasites. Sudden rise of temperature with cyanosis and coldness of the extremities is the predominating clinical syndrome, but the symptoms of congenital malaria may be very varied. The following abortive or larval forms have been described: (1) herpetic form, characterized by vesicular or bullous eruptions on the trunk, face, and scalp; (2) gastro-intestinal form, characterized by vomiting and diarrhoea; (3) nervous form, characterized by restlessness, convulsions, or somnolence. The existence of pregnancy does not contraindicate the use of quinine. On the contrary, the drug should be given freely to every malarial patient during pregnancy as well as to the newborn child as soon as it shows any signs of malaria.

333. Asthma.

P. CANTONNET (*Bull. Acad. Méd.*, February 22nd, 1927, p. 255) suggests that asthma is due to a hypercholesterinaemia which upsets the balance of the equilibrium of the blood colloids, while the excess of cholesterin in the tissues leads to a diminution of sensitiveness of the sympathetic system. Since lipoids can fix mineral salts in the blood increased lipoidal richness of the pulmonary tissue may favour a process of sclerosis which strangles the terminal nerve filaments. In support of this hypothesis Cantonnet adduces the origin of asthma in hepatic deficiency, its increase before menstrual periods and during pregnancy, when the cholesterin percentage of the serum is high, its disappearance in acute infectious diseases and exacerbations of tuberculosis when there is hypocholesterinaemia, its reappearance during convalescence from these diseases, and the special liability of the emphysematous to attacks. He has treated 3,200 asthmatic patients successfully with a series of twenty to twenty-five daily intramuscular injections of iodized polypeptone solution together with a solution of calcium chloride in a jaborandi medium. Nasal sprays and tracheal injections were used locally. In 28 cases the treatment failed completely. Of the 3,000 patients who were subsequently traced two-thirds were definitely cured of their asthma. In the other third 20 to 30 per cent. had one relapse, 10 to 15 per cent. two relapses, 5 per cent. three relapses, 1 per cent. four relapses, while only two or three per thousand had more than four. For prevention of attacks after a cure systematic decholesterinization was aimed at by the administration of various sodium salts; all cholesterin was eliminated from food, calcium chloride was administered for a long period, jaborandi was given, and the functions of the liver were encouraged.

334. Complications of Pertussis.

A. BERARDI (*La Pediatria*, February 15th, 1927, p. 188) reports two cases of severe cerebral symptoms occurring as a complication in whooping-cough. A boy, aged 3½ years, developed convulsions in the second week; these were repeated for two or three days and were followed by slight right facial paralysis, rigidity of the right upper limb, and slight spasm of the right lower limb. The Kernig and Babinski signs were present. On lumbar puncture 20 c.cm. of clear fluid came out under increased pressure. The child

was given a series of vaccine injections and left the hospital quite well after about six weeks. In a boy, aged 9, convulsions started in the second week and were succeeded by slight right facial paralysis, spasm of the left upper limb, and paresis of the left lower limb. The patella reflexes on the left side were much diminished. Clonus and the Babinski and Kernig signs were absent; there was marked dermographism and some slight rigidity of the neck. On lumbar puncture 15 c.cm. of clear fluid was let out under pressure. The patient was given a course of vaccine treatment and completely recovered. In each case the spinal fluid gave evidence of inflammation.

335. Routine Medical Examinations in Athletic Training.

O. JERVELL (*Tidsskrift for den Norske Laegeforening*, February 15th, 1927, p. 165) describes the routine medical examinations of persons in training which were commenced in 1920 by an athletic association in Oslo. By January 1st, 1926, as many as 3,845 males between the ages of 10 and 65 had been examined. Among them there were 665 who were advised either to discontinue athletics altogether or to be careful during training. The fact that as great a proportion as 17 per cent. of the total were in need of advice and restriction of exercise points to the importance of this system of routine medical examination. In as many as 166 cases the fragile build of the person examined was regarded as an indication for limiting exercise, the relation of height to weight and circumference of the chest being considered in connexion with the general appearance. In 28 cases of bronchitis, 1 of asthma, and 4 of pulmonary tuberculosis, athletics were forbidden, and caution in this respect was enjoined on 14 persons with slight pulmonary emphysema, and on 5 with a history of pleurisy. Twenty-two persons suspected of pulmonary tuberculosis were referred to private practitioners. With regard to cardiac arrhythmia, there were 15 cases in which a definite extrasystolic arrhythmia was found, but as in none of these cases was there any sign of organic heart disease training was not forbidden, though those concerned were kept under supervision and were not at first allowed to take part in any competitions. Adventitious heart sounds were heard in 430 out of 3,871 cases—that is, in 11.1 per cent. Among these were 31 showing signs of organic heart disease, which was presumably due in 20 cases to rheumatic fever, in 1 to chorea minor, in one to angina faucium, in 1 to chronic nephritis, in 2 to syphilis, in 1 to lethargic encephalitis, and in the remainder to unknown causes. Among these 3,871 persons there were 60 with a history of rheumatic fever, and of these 60 there were 15 with signs of valvular disease of the heart. There were as many as 348 cases of albuminuria, but only in 7 of them was there definite evidence of renal disease. Phosphaturia was found in 3.7 per cent. of the total, and in more than 5 per cent. of the persons between the ages of 20 and 30 it was not considered as a contraindication to training. Pyuria was found in 23 cases, and in most cases contraindicated athletics.

Surgery.

333. Resection of the Presacral Nerve.

D. FEREY (*Presse Méd.*, February 19th, 1927, p. 227) reports six cases of very severe neuralgia in the sacral and pelvic area, due to cancer, in which the pain was abolished by resection of the sacral nerve. In all these cases large doses of morphine had to be given before any relief could be obtained, but after resection of the nerve all pain disappeared and no morphine was needed. This good result lasted several months. In a sixth case, of atheroma of the aorta in a woman aged 76, who suffered acutely from pelvic neuralgia, the presacral nerve was divided and no pain occurred during four months after operation. Ferey states that the nerve can usually be found near the bifurcation of the aorta, a little to the left of the median line, its most important relation being that with the iliac vein. As a rule no ill effects followed the operation, but in one case some anaesthesia of the middle and upper part of the labia majora was noted. The operation in question has been tried with success in some obstinate cases of dysmenorrhoea.

337. The Mortality from Intestinal Obstruction.

T. ERLUND (*Finska Lakaresällskapets Handlingar*, January, 1927, p. 24) analyses 140 cases of mechanical intestinal obstruction treated in the general hospital at Tammerfors between January 1st, 1911, and November 1st, 1926. There were 93 males and 47 females; among the former there were 44 deaths and among the latter 10, the total of 54 deaths representing a mortality of 38.6 per cent. It is shown that this mortality does not compare unfavourably with that of various large hospitals in recent times. Thus, in 1925, Perthes admitted a mortality of 35 per cent. (200 operations), Bier had 107 deaths among 200 cases, and Körte, in three series of cases, had a mortality of 53, 30, and 40 per cent. respectively. Guillaume's French statistics, published in 1921, showed a mortality of 63 per cent., and Horine's statistics from the University Hospital in Maryland a mortality of 52 per cent. In Eklund's series there were 69 cases of intestinal obstruction caused by adhesions, the number of deaths in this class being 16. Among the cases of volvulus there were 13 affecting the small intestine, 15 the caecum and colon, and 21 the sigmoid flexure. There were 12 cases of intussusception, 6 of intestinal knots, and 4 of internal incarcerated hernia. The author concludes that, as the mortality among his cases compares favourably with that of several first-class hospitals outside Finland, reform of conditions within his institution is not likely to improve matters appreciably. But he believes that the mortality could be halved if patients were sent earlier to hospital, and he recommends education of the public in this connexion. He draws attention to the delay often caused by medical practitioners not visiting patients in the morning, which is commonly devoted to attendance in the surgery.

338. Rupture of Abdominal Incisions.

L. FREEMAN (*Archives of Surgery*, February, 1927, p. 600) discusses the cause of post-operative rupture of an abdominal incision, which may occur a week after operation, and is generally attributed to the giving way of sutures or to strains such as vomiting. Infection may account for some cases, while failure of the healing process has been suggested. The formation of a haematoma may weaken a wound, but its pressure is hardly likely to separate the fascia. He thinks that these causes may be contributory, but do not appear to be the main factors, and he attaches more importance to inadequate closure of the peritoneum. Between the loose stitches the omentum forces itself, and in expanding acts as a wedge, which separates the tissues and prevents proper union. A rupture may then be precipitated by vomiting or distension. If rupture occurs from within the danger can be lessened by care in closing the peritoneum; the sutures should be placed close together. Post-operative hernias are similarly explained by subcutaneous wound rupture, which is more common than complete rupture.

339. Volvulus of the Stomach.

M. G. JEAN (*Bull. et Mém. Soc. Nat. de Chir.*, February 5th, 1927, p. 110) records a case of the rare partial volvulus of the stomach in a woman aged 31. She had previously had indefinite abdominal pain and had been regarded as a case of visceroptosis. Prior to the operation the condition had been provisionally diagnosed by x rays and the presence of a mobile tumour was discovered. At the operation a partial volvulus was discovered, the posterior surface of the stomach being anterior and covered by the transverse mesocolon, the transverse colon itself having been carried round with the greater curvature. The organ was untwisted and normal relations were restored, the stomach being then fixed in position. Such a condition is seldom recognized before operation. The volvulus in this case was probably secondary to the general visceroptosis and relaxation of the ligaments, which, associated with some alteration in the abdominal pressure, following a meal, and accompanied by active peristalsis, favoured the production of the condition. It is added that after detorsion in such a case it seems advisable to perform some type of gastropexy to prevent a recurrence of the volvulus.

340. Carcinoma of the Stomach.

G. B. EUSTERMAN and W. H. BUEERMANN (*Journ. Amer. Med. Assoc.*, January 29th, 1927, p. 295), considering the present position of diagnosis and prognosis of gastric carcinoma, conclude that the time has come for revision of the traditional conception of this condition, so that pace may be kept with the clinical and histological information now being obtained from patients who undergo operations. Delay in diagnosis is attributed to procrastination, incomplete examination, failure of both the patient and his medical attendant to appreciate the gravity of a dyspepsia commencing in middle or late adult life, and the obsolete teaching of the textbooks. The authors advocate team work for diagnosis, and estimate that one person in four has an operable lesion. The simulation of simple ulcer is said to be much commoner than is generally supposed, for every gastric ulcer is potentially malignant. It is noteworthy that 8 per cent. of carcinomatous ulcers occur in subjects under 40 years of age. Increasing skill in the diagnostic use of x rays diminishes the need of other investigations, including exploratory operations. The more important diseases simulating cancer of the stomach are such intrinsic conditions

as gastric syphilis, lymphosarcoma, and benign tumour; extrinsic affections including carcinoma of the pancreas, duodenum, and gall bladder; and constitutional disorders, of which pernicious anaemia is the most important. Much has been done in pre-operative preparation of patients and in the administration of the anaesthetic. Apart from extensive spread of the disease or metastases, the most unfavourable occurrence as regards operative intervention is perigastric lymphatic involvement. The authors report that of patients without this involvement 52.5 per cent. were alive and well three years subsequent to the operation, but with lymphatic involvement there is a very marked reduction in the percentage, the survival figure falling to 18 per cent.

341. Recurrent Jejunal Ulcer following Gastric Resection.

J. HOLST (*Norsk Mag. f. Laegevidensk.*, February, 1927, p. 111) records the case of a man, aged 23, who, on account of duodenal ulcer, had undergone Polya's resection of the ulcer and pyloric part of the stomach. Nine months after the operation perforation of a jejunal ulcer occurred. The anastomosis was resected, together with 3 cm. of the fundus of the stomach and 15 cm. of the jejunum, including the perforation and entero-anastomosis, only one-third of the stomach being left. The amount of free hydrochloric acid was reduced to 9 and the total acidity to 20. Microscopical examination of the wall of the stomach left *in situ* showed the characteristics of the mucous membrane of the fundus. Eleven months after the second operation another jejunal ulcer perforated and excision was performed. Since the third operation, which was performed a year ago, the patient has been in good health. The case shows that resection of two-thirds of the stomach, including the pyloric portion and entailing a considerable reduction of the gastric acid, does not prevent the formation of post-operative jejunal ulcers.

342. Acute Pancreatitis.

PICOT (*Bull. et Mém. Soc. Nat. de Chir.*, February 16th, 1927, p. 198) discusses two cases of acute pancreatitis reported by J. Charles-Bloch. This condition is seldom diagnosed before operation; one of these cases was regarded as acute intestinal obstruction, the other as peritonitis. They were marked by a very rapid and acute onset with distension and complete obstruction. There was no rigidity. In one case the pain was referred to the left iliac fossa and was attributed to a volvulus. The other patient had pain chiefly in the epigastrium radiating to the left flank. The chief features in these cases were the violent pain and the rapid onset of meteorism. The pulse rate was 120, and the temperature 100.4°. The general condition became rapidly worse, and in this respect differed from obstruction. In the history there was nothing to suggest intestinal trouble, but in both cases there was a suggestion of previous gall-bladder trouble. The treatment of the condition is drainage of the pancreas, and the drain must be retained in position for several weeks. In one case it was removed early and the patient died with a subphrenic abscess. If the gall bladder is distended or there are gall stones, the gall bladder should be drained. Picot concludes that if this condition was more often remembered its occurrence would be more often recognized.

343. Prostatectomy in Two Stages.

ROCHET (*Journ. d'Urol.*, January, 1927, p. 5), discussing the surgical treatment of chronic retention of urine due to enlarged prostate, holds that a temporary cystotomy, as a preliminary to removal of the prostate, is not always desirable. This method has been condemned by some surgeons and is not acceptable to many patients. It has distinct disadvantages where it has been present for some time when the second operation is undertaken. The abdominal wall becomes hard and indurated round the scar. This renders the removal of the prostate more difficult, while the gland itself, after drainage of the bladder, becomes shrunken and fixed in position. Cases of chronic retention may be divided into three groups. In the first there is incomplete retention without infection or renal failure, and an operation is performed to do away with the trouble of catheterization. In the second group there is retention and distension of the bladder. Here again the urine may be clear, but there is impaired renal function with evidence of nephritis. In the third group there is retention complicated with infection and possibly evidence of uraemia due to pyelonephritis. In the first group an immediate prostatectomy may be performed with little danger. In the second group a two-stage operation will be advisable, while in the last a perineal drainage of the bladder is the best and safest treatment. If severe haemorrhage follows the cystotomy an urgent and rapid removal of the prostate may be necessary in a few cases.

Therapeutics.

344. Sanocrysin in Pediatrics.

G. SCHELTEMA and H. E. ROOKMAKER (*Nederl. Tijdschr. v. Geneesk.*, February 5th, 1927, p. 702) employed sanocrysin in 15 cases of pulmonary tuberculosis at the Groningen Children's Hospital, and in 4 obtained a remarkable and extremely rapid improvement, both as regards the symptoms and the physical signs and *x*-ray appearances. No bad effects could be attributed to the treatment apart from slight rise of temperature and transient albuminuria. In 7 cases some improvement was observed, but not of any considerable degree, nor confirmed by *x*-ray evidence, and in 4 cases of miliary tuberculosis no benefit of any kind was detected. The results, however, as a whole were thought to be sufficiently satisfactory to make further trial of sanocrysin in children suffering from pulmonary tuberculosis desirable.

345. X-Ray Treatment of Pertussis.

W. M. SHERIDAN (*Radiological Review*, January, 1927, p. 5) in the course of a year has treated with *x* rays 22 patients suffering from whooping-cough. Only one failed to improve, 11 showed abortion of the disease and marked improvement within a few days, and the rest were rather better in one or two weeks. Nearly all the cases were very severe and most patients had been whooping for two or three weeks. No deaths occurred. As a rule the shorter the duration of the disease and the younger the patient the better were the results obtained. The average total leucocyte count on admission was 16,411, with 58.1 per cent. lymphocytes. Within a week following *x*-ray treatment nearly every case showed a reduction in the total cell count and in the percentage of lymphocytes. *X*-ray films taken before treatment showed peribronchial thickening and enlargement of the tracheo-bronchial lymph glands. In severe cases there was also mottling of the lung, suggesting early bronchopneumonia. Films taken two weeks after *x*-ray treatment showed less peribronchial thickening and a definite diminution in the size of the tracheo-bronchial glands.

346. Diathermy in Tonsillar Hypertrophy.

F. G. HUELBES (*Arch. med., cir. y esp.*, January 8th, 1927, p. 44) maintains that diathermy is superior to all other methods for treating enlarged tonsils, especially as it avoids the occurrence of haemorrhage, which is one of the greatest dangers inherent in tonsillectomy. Another drawback to excision of the tonsils is the post-operative period, during which the patient must keep in his room or at least remain on fluid diet to prevent the occurrence of haemorrhage or infection. On the other hand, diathermy is a bloodless operation which lasts no longer than a minute, does not require constant post-operative attention or interfere with the patient's ordinary life or diet. The diathermy is preceded by anaesthetizing the tonsil with a 6 per cent. solution of cocaine, reinforced in the case of timid patients or very large tonsils by a deep injection of 1 per cent. solution of novocain and adrenaline. Two sittings are required, one for each tonsil, the interval between the two being eight to ten days.

347. Ultra-violet Rays in Pulmonary Tuberculosis.

H. J. GERSTENBERGER and C. W. BURHANS (*Amer. Journ. Dis. Child.*, January, 1927, p. 54) report seven cases of pulmonary tuberculosis in infants in which distinct improvement and recovery followed treatment by ultra-violet rays from the quartz mercury lamp. In order to evaluate the therapeutic power of the actinic rays the patients were kept in bed and indoors, exposure to outside air, sunlight, and the carbon arc light being avoided. Previous experience in treating tuberculous peritonitis and tuberculosis of the mesenteric glands with a quartz lamp convinced the authors that the actinic rays had a distinct therapeutic value in such cases. While rest in bed, dieting, and cod-liver oil improved the nutrition of the patients the authors think these measures were not entirely responsible for the success of the treatment, exposure to ultra-violet rays being of value in bringing about a change of disposition and a more consistent progress towards recovery. The patients were kept under observation for one to two years, and the experience gained showed that pulmonary exudates, which were massive in character and lobar in distribution, were especially likely to improve. Full notes, with *x*-ray plates and temperature and weight charts, of the seven patients are given. Each one was exposed to quartz lamp irradiation at least three times a week, and in some cases there were cavities in a dense right upper lobe. It is sugges.ed

that the good results obtained may be due mainly to the fact that such massive infiltrations represent a valuable beneficial immunologic attack of the body against the tubercle bacillus rather than that they are the result of local tissue irritation by the tubercle bacillus.

348. Serotherapy in Scarlet Fever.

C. ZOELLER (*Bull. Soc. Méd. des Hôp. de Paris*, February 10th, 1927, p. 115) reports two cases of scarlet fever successfully treated by an antitoxic serum prepared by O'Brien. The first patient was still suffering from pulmonary congestion after influenza when he developed a bad sore throat, a typical scarlet fever rash, and a temperature of 103.6°. He was given 20 c.cm. of the serum, and next day the temperature had fallen to 100°, the pulse from 120 to 100, the rash had disappeared, and the throat was much less troublesome. The temperature remained down and no further symptoms appeared, except some passing articular pain and fever on the ninth day, due to the serum, and slight desquamation on the eighteenth day. In the second patient marked albuminuria followed previous attacks of measles and tonsillitis, and some weeks later he showed definite signs of scarlet fever. He was given 20 c.cm. of the serum, and on the next day another injection of 10 c.cm. The rash completely disappeared on the third day, and by the seventh day the patient was convalescent. On the second day the urine contained 6.2 grams of albumin per litre; next day the albumin fell to 0.6 gram per litre, and on the fifth day there was no trace of albumin. In the urine examined before the serum was given streptococcal toxin was detected; this was not present subsequently.

349. Malarial Treatment of Leukaemia.

C. J. GAMBLE (*Journ. Amer. Med. Assoc.*, January 8th, 1927, p. 87) has investigated the therapeutic value of tertian malaria in two patients, one with lymphatic and the other with myelogenous leukaemia. They were inoculated with a strain of *Plasmodium vivax* which had already been used for therapeutic purposes and shown to be promptly curable by quinine; 5 c.cm. of blood from a patient in the paroxysmal stage were injected intramuscularly. The blood of the patient with lymphatic leukaemia was used to infect the myelogenous patient. Both were allowed to have a series of febrile paroxysms, and in each there was a fall in leucocytes to less than half the original number, but, following the termination of the paroxysms by quinine, the white cell count rose in six and three days respectively to approximately its previous level. In the lymphatic case a marked haemolytic effect was produced, the red cells falling from 2,460,000 to 1,520,000 and the haemoglobin from 47 to 30 per cent.; the use of quinine did not bring about a rapid return to the previous level. In the myelogenous case this effect on the erythrocytes and haemoglobin was not so pronounced. During the year following the injection of blood from the lymphatic into the myelogenous case there was no evidence of transmission of the lymphatic leukaemia. Gamble concludes that while tertian malaria during the stage of paroxysms markedly decreases the leucocyte count in both types of leukaemia it does not appear to have any permanent curative effect.

350. Quinidine Sulphate in Auricular Fibrillation.

N. SIDEL and F. G. DORWART (*Boston Med. and Surg. Journ.*, February 10th, 1927, p. 216) record a series of twenty unselected cases of auricular fibrillation to demonstrate the desirability of treating the condition with much larger doses of quinidine than are usually administered. They think that the drug should be used to supplement and not to supplant digitalis. All but one of their patients had become compensated with digitalis, rest, and morphine before quinidine was started. In the series of twenty cases quinidine sulphate produced regular rhythm in thirteen (65 per cent.), and in all patients with a cardiac history of two years or less. Treatment commenced with two test doses of 3 grains at a four-hour interval, followed, if no idiosyncrasy manifested itself, by five doses daily of 6 grains at three-hourly intervals for from three to five days. If at the end of that time fibrillation still persisted 10 grains were given three times a day for one day and then four times a day for two days, and if necessary five times a day for a further two days, up to, finally, 15 to 40 grains five times a day. It is added that when quinidine is given in large amounts in gradually increasing doses the patient should be under observation in hospital. The highest single dose was 45 grains, the highest daily dose 200 grains, and the highest total dosage over a period of two months 3,381 grains. While large amounts are not advocated, it is clearly shown that they can be employed, if divided up, in cases where small quantities have failed.

Ophthalmology.

351. Paresis of Convergence following Encephalitis Lethargica.

W. F. HOFFMAN (*Amer. Journ. of Ophthalmol.*, November, 1926, p. 823) describes seven cases of this condition following encephalitis lethargica. In some of these cases diplopia was noticed from the first, but as a whole it was a sequel rather than a concomitant of the initial attack. In no case was there any paralysis of any muscle, but rather an inability to perform the act of convergence. The pupils, however, in all cases reacted to accommodation. Paralysis of the function of divergence, causing diplopia for distance, was a marked feature of the encephalitic cases of the spring of 1924, but paralysis of convergence does not seem to have been previously reported in association with encephalitis lethargica.

352. Endophthalmitis from Retained Foreign Body Cyst.

D. T. VAIL, jun. (*Arch. of Ophthalmol.*, January, 1927, p. 5), describes the case of a young mechanic who had a unilateral cataract, the result of an intra-ocular foreign body. The foreign body, which was a particle of steel, was brought forward into the anterior chamber by the giant magnet and subsequently removed by a keratome section. Soon afterwards the eye became severely inflamed and a hypopyon appeared. A few days later a yellowish vesicle attached to the anterior surface of the lens was visible. The eye became steadily worse in spite of treatment, which included intramuscular milk injections. A week later an iridectomy was performed and the cataract removed, after which the eye speedily quieted down with good vision resulting. Examination showed a yellowish cyst attached to the lens. This cyst had contained the foreign body, and after removal of the foreign body the cyst had produced this marked inflammatory reaction in the eye. Animal and cultural experiments for pathogenic organisms were negative, as also was a skin test with lens protein.

353. Iris Reposition in Cataract Extraction.

R. FOSTER MOORE (*Brit. Journ. of Ophthalmol.*, January, 1927, p. 10) describes a manœuvre for dealing with the iris when it slips in front of the knife in making the section of the cornea in an extraction. When this happens before the section is completed, if a repositor is taken and with it stroking movements are made on that part of the cornea which overlies the blade, the iris can be expressed from between the blade and the cornea and be made to slip under the knife; the section can then be completed in the ordinary way.

354. Intra-Ocular Sarcoma in Children.

W. P. PARKER and W. H. STOKES (*Journ. Amer. Med. Assoc.*, December 4th, 1926, p. 1891) report ten cases of intra-ocular sarcoma in children, in which fourteen eyes were clinically affected. In eight cases the history showed no evidence of heredity, and in two the history was unknown. In six cases the orbit was subjected to α-ray treatment after exenteration; in three recurrence and death occurred, in two there was no recurrence, and in one the result is unknown. A clinical diagnosis of glioma was made in all but one case, which was treated for tuberculous uveitis, but was proved six months later to be sarcomatous. The authors state that nothing definite is known of the etiology of intra-ocular neoplasms in children. The work of certain investigators indicates the possibility of a retinal origin of these so-called gliomas, and there is a probability of the occurrence in the retina of growths of mesoblastic origin. These malignant growths may be either retinal or choroidal in origin; they are non-pigmented, and in a number of cases show rosette formations. The growth characteristics are the same, and they are all highly malignant. According to Parsons, the rosettes are aggregates of rod and cone fibres. The basal membrane represents the membrana limitans externa, the protoplasmic protrusions into the lumen are rods and cones, and the nuclei are the outer granules. The distinction between a retinal and choroidal malignant tumour occurring in children is difficult, and pathological knowledge is still insufficient to justify positive conclusions. Most writers agree that a glioma of the retina has nothing in common with one of the central nervous system. Retinal gliomas are found only in the young, while gliomas of the brain and cord occur at all ages; choroidal malignant growths have been reported in both adults and children. Summarizing their cases, the present authors state that pathological examination proved the growths to be sarcomatous and to possess properties of angioblastic proliferation. The apparent rosette structure, seen in only two cases, represents early perithelioma tous proliferation; it is due entirely to the proliferation of the

cells arising from small blood vessels and is not characteristic of epiblastic tumours. In older portions of the neoplasms this arrangement is absent. The authors claim that further study is necessary to prove that a glioma or neuroepithelioma does not exist as a clinical entity in children.

355. Refraction without Mydriasis.

DORLAND SMITH (*Amer. Journ. of Ophthalmol.*, December, 1926, p. 896) in this article advocates a method of estimating errors of refraction without the use of a mydriatic, which he terms "cyclodamia." The complete test includes the successive stages of examination of the media and fundus, the measurement of the best distant vision obtainable, ophthalmometric examination, skiascopic examination, and subjective testing, with particular attention to the obtaining of as full accommodative relaxation as possible.

Obstetrics and Gynaecology.

356. Placenta Accreta.

D. S. FORSTER (*Canadian Med. Assoc. Journ.*, February, 1927, p. 204) reports a case of placenta accreta, which has been estimated by Polak as occurring in 1 in 6,000 deliveries; the present case was the only one among 8,000 deliveries at the Montreal Maternity Hospital during the past six years. In this condition, as the result of absence of decidua at the placental site, the villi penetrate the uterine muscle and make separation impossible; it differs thus from other forms of adherent placenta, where there is invariably a decidua basalis. The predisposing causes are repeated or too vigorous curetting, endometritis, submucous fibroid, and previous manual removal. In Forster's case a Jewish woman, aged 32, had had three previous pregnancies, none being instrumental, but her second child was born dead following a blow on the mother's abdomen, and on this occasion the afterbirth was removed with instruments. In the case of the third child the placenta had to be removed manually; there was much bleeding, and a two months' confinement to bed. When her fourth pregnancy reached term the blood pressure was 132/82, there was a trace of albumin in the urine, some backache, and slight bleeding from the vagina. She gave birth to a dead foetus, difficulty being experienced in removing the after-coming head. The placenta did not follow, expression under anaesthesia failed, and efforts at manual removal only tore away two small cotyledons. Hysterectomy was therefore performed. The placenta covered the whole of the interior of the uterus; it was variable in thickness and the normal line of cleavage could not be found. The absence of decidua was demonstrated by histological section. Forster agrees with Polak that hysterectomy is the proper treatment of this condition.

357. Gonorrhoea in Women.

A. SIREDEY (*La Gynecologie*, December, 1926, p. 705) remarks that the search for the gonococcus is of little diagnostic value in the female except in acute gonorrhoea; in the more common form which is chronic from the beginning it is rarely found, being replaced by other pathogenic organisms and saprophytes. Acute gonorrhoeal metritis is rare and results from infection by a male suffering from acute gonorrhoeal urethritis; it usually occurs in young prostitutes, as an immediate sequel of marriage, or in married women whose husbands have recently returned after absence. The symptoms include vulvo-vaginal redness and pain, dysuria, hypogastric pain, and pyrexia; hypersensibility renders vaginal examination very difficult, and acute adnexal or peritoneal reactions are not uncommon within a few days of infection. Examination a few days later shows a red desquamated cervix bathed in pus. Apart from microscopical examination the concomitant existence of purulent urethritis is of diagnostic importance. Subacute gonorrhoeal metritis is more common, and may or may not follow an acute stage; vaginal examination being easier, its detection is less difficult. Gonococci in the secretions gradually diminish in abundance, and later are only to be detected immediately before or during the two or three days following menstruation. Chronic gonorrhoeal metritis is much the most common, but —especially when chronic from the first—is often unsuspected by the patient, to whom it reveals itself by but one definite symptom—namely, leucorrhoea. The leucorrhoea of chronic gonococcal infection is characterized by intermittent loss (especially on rising in the morning, after walking, or after standing) of thick, tenacious, greyish or opal-coloured fluid. Sterility is common, and it is very rare to detect the gonococci microscopically. Vaginal examination shows a mobile uterus which is neither enlarged nor tender, and a swollen cervix which in a nullipara is conical, with a small orifice surrounded by a congested zone and emitting on pressure a characteristic greyish glairy mass. Such a condition may persist almost indefinitely, causing sterility, of which the origin is often unsuspected by the medical adviser; usually the husband has been infected some years before marriage and has apparently good reasons for believing himself cured. Secondary extragenital infections are common after acute and subacute gonorrhoeal metritis, but in the chronic forms are rarely encountered save as a sequel to surgical or instrumental manœuvres on the cervix. In the treatment of chronic cervical gonorrhoea Siredey prefers to Schröder's or other resections of the cervical mucous membrane the use of a diffusible caustic introduced by Richelot and consisting of two parts of potash to one of lime. By successive applications of this at about ten days' interval, and lasting twenty to thirty seconds or more, the diseased glands and mucosa of the cervix are eliminated. It is admitted that the applications, if sufficiently radical to be effective and sufficiently conservative to avoid the risk of inconvenient or dangerous cicatrices, demand considerable skill, experience, and judgement; they must not be employed in acute or subacute cases, in the presence of pyrexia, or when the adnexa are at all swollen or painful. To avoid stenosis of the os or cervical canal the patient must be carefully watched for a month after this treatment, and the introduction of olled bougies may be required. The author regards these caustic applications as the best treatment for chronic gonorrhoea, but thinks that diathermy after further trial may prove to be a valuable adjuvant or substitute.

358. Treatment of Eclampsia.

A. HOCHENBICHLER (*Zentralbl. f. Gynäk.*, February 19th, 1927, p. 486) gives an account of the treatment of eclampsia in the Third Maternity Hospital in Vienna, from the beginning of 1910 to the end of 1926. During that time 275 patients were treated. Until the middle of 1922 the mortality, in spite of energetic treatment by the usual methods, continued to vary from 15 to 20 per cent., the statistics merely showing a slightly lower mortality in primiparae, and also in cases in which there was no operative intervention. In July, 1922, the author began to treat his patients with ultra-violet rays, using a quartz lamp; of the 64 women admitted since then 37 have been treated with ultra-violet rays, with a mortality of 2 (5.4 per cent.). In 10 cases with no deaths the only treatment given was light; in the remaining 27 it was combined with morphine, luminal, or chloral, or with venesection and intravenous or subcutaneous injections of saline or Ringer's solution. Labour was induced by de Ribes's bag, rupture of the membranes, or bringing down a leg, according to the suitability of the case, and forceps applied, or craniotomy performed on a dead child as soon as dilatation was complete. The patients received a ten minut s' exposure of the whole body (five minutes each side), the face, breasts, and genital area alone being protected by a gauze covering; this was given as soon as possible after admission, under a light ether narcosis and at a distance of 1 metre from the lamp. A further ten minutes' exposure was given at a distance of 1½ metres after about five hours, and this was repeated the next day, not more than two exposures being given in twenty-four hours. The chief result of this method of treatment, and the one to which Hochenbichler attributes its success, is an instantaneous fall of blood pressure after the first exposure, often from 200 to 50 c.mm., due to dilatation of the surface blood vessels, the heart and lungs being thereby much relieved; general metabolism is also stimulated. The author suggests the prophylactic use of ultra-violet rays during late pregnancy for pre-eclamptic cases.

359. Uterine Fibroma and Pregnancy.

V. AZA (*La Med. Ibera*, February 5th, 1927, p. 146) records a case showing that operations can be performed in pregnancy, not only on organs anatomically and physiologically connected with the uterus, such as ovaries with cystic formation, but even on the uterus itself, without in any way interfering with the normal course of pregnancy. The patient was a primipara, aged 42, who in the third month of pregnancy developed severe pain in the right abdominal quadrant. The diagnosis lay between extrauterine pregnancy and a new growth of the right adnexa. On laparotomy a round tumour the size of a large coco-nut with torsion of its pedicle towards the left was found attached to the right side of the uterus, which corresponded to that of a three months' pregnancy. The tumour was successfully removed and subsequent recovery was uneventful. Histological examination of the tumour showed that it was a fibroma without the slightest trace of malignant desquamation. At the time of publication, three months after the operation, the pregnancy was proceeding normally.

Pathology.

360. Local Production of Immune Bodies in the Meningeal Cavity.

S. MUTERMILCH (*C. R. Soc. de Biologie*, February 18th, 1927, p. 397) records some experiments on the local production of agglutinins to bacteria introduced into the cerebro-spinal fluid. One series of rabbits was injected intraperitoneally with a cholera vaccine; another set received the same dosage into the subarachnoid space. In all the animals the serum developed an agglutinin titre to *V. cholerae* of 1 in 1,000 to 1 in 5,000, but the agglutinin titre of the spinal fluid of those rabbits injected intraperitoneally was *nil*, though in those in which the organisms had been introduced into the subarachnoid space it was 1 in 800 to 1 in 1,600. This indicates that antibodies in the serum are unable to gain access to the spinal fluid, and suggests that the antibodies found in the spinal fluid of those animals which were injected by the subarachnoid route must have been formed locally. In a second experiment one series of rabbits was injected intraperitoneally with the cholera vibrio and intraspinally with the typhoid bacillus; another series was injected intraperitoneally with the typhoid bacillus and intraspinally with the cholera vibrio. The results showed that the serums of all the animals agglutinated both organisms, whereas the spinal fluid agglutinated only that species of organism which was injected into the subarachnoid space. In another experiment rabbits which had been vaccinated intraperitoneally with the cholera vibrio were given an intravenous injection of urotropine. The spinal fluid of these animals collected from twenty minutes to six hours later was found to contain a small quantity of agglutinins—about 1/400 or 1/500 of the amount present in the serum. In another experiment rabbits which had been vaccinated intraperitoneally with the cholera vibrio were injected intraspinally with 0.5 c.cm. of 10 per cent. suspension of flour in saline. The agglutinating power of the spinal fluid of these animals reached a point equivalent to about one-tenth of the serum titre. The author concludes that agglutinins may be formed locally in the meningeal cavity; these agglutinins may then pass into the blood serum. But agglutinins formed in the blood serum are unable to pass into the spinal fluid unless an injection of urotropine is given or an aseptic meningitis is set up.

361. Variations in the Amylolytic Power of the Blood and Urine.

A. GUALDI (*Il Morgagni*, February 6th, 1927, p. 201) has investigated the amylolytic power of the blood serum and the urine in a number of pathological conditions. The fluid to be tested was put up in ascending dilutions in small test tubes with 1 per cent. sodium chloride solution and a 0.1 per cent. solution of cooked starch. After shaking, the tubes were incubated at 37° C. for half an hour, then cooled rapidly, and to each was added a drop of N/50 solution of iodine. The smallest amount of fluid that just served to digest the starch was taken as the index of amylolytic power. The amylolytic activity of the blood serum throws light on the functional condition of the pancreas; the simultaneous examination of the amylolytic powers of the serum and the urine indicates the extent of renal permeability. In pulmonary tuberculosis it was found that the results obtained depended on the gravity of the disease. In mild cases or in cases that were doing well the amylolytic titres of the blood serum and urine were within the normal range of variability, that of the urine being generally higher than that of the serum. In severe cases the titre of the serum was higher than normal, and the titre of the urine not only lower than normal but lower than that of the serum. The author therefore thinks that this test may be of value in the prognosis of pulmonary tuberculosis. In exudative pleurisy, chronic bronchitis, bronchial asthma, gastric and duodenal ulcer, typhoid and paratyphoid fever, and certain other conditions, the serum and urine titres were within normal limits. In epidemic parotitis, however, the serum titre was always increased.

362. A Streptothrix in the Meningeal Fluid.

M. GERBASI (*Centralbl. f. Bakt.*, February 5th, 1927, p. 369) has isolated six strains of a streptothrix from the cerebro-spinal fluid of children suffering from purulent meningitis in Palermo. The rod-shaped organisms, of varying length, stained irregularly, and resembled the diphtheria bacillus. They refused to grow on agar or in broth, even when glycerol was added, but growth occurred both under aerobic and anaerobic conditions in media containing animal proteins such as serum, blood, and ascitic fluid, and also occurred in dextrose broth, a slight turbidity appearing after three days. In culture the organisms appeared as non-motile, Gram-up into two to five short segments; they were arranged in groups, palisades, and V-forms, and granular staining was common. In old cultures coccoid forms were seen. Branching was never observed. The organisms produced acid in glucose and galactose. Inoculated subcutaneously into guinea-pigs they sometimes caused death in about a week, preceded by cachexia and general malaise. The local lymph glands were enlarged, the suprarenals were congested, and small haemorrhages were found in the central nervous system. Direct injection of the organism into the subarachnoid space was without effect. A filterable toxin was formed, producing much the same symptoms on inoculation into guinea-pigs as did the injection of whole cultures. Serums prepared by injection of rabbits with heated cultures agglutinated all six strains. This organism resembles the members of the Actinomyces group in certain respects, particularly in its low virulence to animals, but the author was unable to identify it with any particular species of this group. On the other hand, it agrees closely with the organisms previously described by Rutelli, Sindoni, and Fonzo, which were similarly isolated from the meninges. Gerbasi gives it the name *Streptothrix meningea*.

333. Effect of Quinine on Phosphorus Metabolism in Man.

T. A. HUGHES and D. L. SHRIVASTAVA (*Indian Journ. Med. Res.*, January, 1927, p. 601) report that the administration of quinine, orally or intravenously, causes a lowering of the blood sugar content, and that this hypoglycaemia is due to an excessive liberation of insulin. Phosphorus plays an important part in carbohydrate metabolism, and the relation of phosphorus to the breaking down of carbohydrates in muscle has been demonstrated by Embden and his co-workers. It is generally agreed that insulin and adrenaline cause lowering of the inorganic phosphates of the plasma and urine, followed by a rise, and whatever the nature of the process whereby the blood inorganic phosphates are used up during carbohydrate metabolism, the change is only temporary. The authors conducted two series of experiments, in which 10 or 15 grains of quinine, alone or followed in fifteen minutes by 1 c.cm. of pituitrin subcutaneously, was administered to both normal individuals and hospital patients. Their results show that quinine in antimalarial doses causes a retention of phosphates. This fact is evidence of the interference of this drug with carbohydrate metabolism, resulting in a fall in blood sugar and an increased output of insulin. The investigations of Brittin and of Clarke indicate that quinine produces its effect on the circulating glucose by acting as a stimulant of the parasympathetic system. While the fall in blood sugar after the administration of quinine can be prevented by the previous ingestion of carbohydrates, this does not reduce, but rather tends to augment, the effect on the islet tissue. When, therefore, quinine is administered in large doses over long periods, as in malaria, it is acting more or less continually as a stimulant of the pancreatic islets, and since overstimulation of this tissue is known to produce exhaustion, it is not unlikely that in many cases quinine plays a part in the production of a diabetic condition.

364. A Specific Flocculation Reaction for Pneumococci.

C. W. JUNGEBLUT (*Journ. Exper. Med.*, February 1st, 1927, p. 227) states that, though numerous flocculation reactions for the sero-diagnosis of syphilis have long been recognized, the action of bacterial lipoids in a specific flocculation reaction was not studied until in 1924 de la Rivière and Roux described flocculation occurring between alcoholic extracts of meningococci and antimeningococcus serum, and suggested the value of this reaction in the standardization of anti-meningococcus serum. More recently they have included the gonococcus in their studies. Georgesco has reported the application of the same method to the sero-diagnosis of cerebro-spinal meningitis and typhoid fever. Jungeblut now reports the existence of a similar reaction between pneumococci and antipneumococcus serum, and discusses the question whether this reaction is both species-specific and type-specific. The bacterial antigens were prepared by extracting the centrifugalized, washed sediment of 1,500 c.cm. of an eighteen-hour pneumococcus broth culture in 40 c.cm. of absolute or 95 per cent. ethyl alcohol for four weeks at room temperature. These extracts were filtered through paper, and were then ready for use. A 10 per cent. alcoholic extract of Sumatra benzoin was used as a non-specific reinforcing agent, and monovalent antipneumococcus serums, obtained from horses immunized by various methods, were employed. Jungeblut maintains that a flocculation reaction does occur between alcoholic extracts of pneumococci and antipneumococcus serum, and that this reaction appears to be species-specific, but not strictly type-specific. The flocculating power of the serum does not develop to any extent before the end of the fourth or fifth month, and some relation appears to

EPITOME OF CURRENT MEDICAL LITERATURE.

Medicine.

385. Prevention of Measles by Immune Goat Serum.

R. TUNNICLIFF and A. L. HOYNE (*Journ. Amer. Med. Assoc.*, December 25th, 1926, p. 2139) immunized goats by intravenous injection of green-producing measles diplococci and their filtrates, and thus obtained an antibacterial and antitoxic serum. Injections of 4 to 6 c.cm. of the serum were given to children aged 1 year and over and to a few nurses with a negative history of measles, after definite exposure to the disease. All who did not receive serum and those who had it five days or more after exposure developed measles. Goat serum, however, prevented measles in 45 per cent. of those injected with it on the fourth day after contact with measles patients and in 97 per cent. of those who received it within the first three days after exposure. Eleven infants under 1 year of age who received the serum later than the fourth day after exposure all developed measles, but 33 infants, of whom 10 were over 6 months old, and who were given serum within the first four days after exposure, showed no signs of the disease. Local and general serum reactions occurred in only 12 per cent. of those injected. The authors hold that, though the duration of passive immunity conferred by immune goat serum is only a few weeks, the serum is useful in preventing measles in very young and sick children and in stopping epidemics in institutions.

386. Convulsions in Whooping-cough.

E. HÄSSLER (*Jahrb. f. Kinderheilk.*, December, 1926, p. 376) states that only a few data are available as to the frequency of convulsions in whooping-cough. Heubner observed this complication in 6 out of 187 cases, and Eckert in 25 out of 476 cases. Hässler states that during the last epidemic at Dresden severe general convulsions were observed in 14 out of 67 infants and in 8 out of 53 young children—an unusually high percentage; 11 of the 22 patients died, 10 of them had pneumonia also. Of the 11 who recovered 5 were infants and 6 young children. The relatively favourable results are attributed by Hässler to the use of strontium chloride and urea, which was given intramuscularly every two or three days in doses of 1/2 to 1 c.cm. The effects of the administration of strontium were a general diminution of irritability without undesirable cerebral complications, a tonic action in the heart, and prevention of hypostatic pneumonia. Seven illustrative cases are recorded.

387. Pulmonary Abscess.

ACCORDING to F. BEZANÇON, A. JACQUELIN, and J. CÉLICE (*Bull. et Mém. Soc. Méd. des Hôp. de Paris*, February 3rd, 1927, p. 92) pulmonary abscess rarely develops as an ordinary acute infection; more often there are grave general signs, the abscess cavity seldom heals, and the condition usually passes into chronic subacute infection, interrupted by the periodical retention of pus. They report, however, the case of a man, aged 24, in whom a central cavity developed and healed in a month; it would have escaped observation but for a skiagram. His symptoms were cough, expectoration, and thoracic pain. There was increased vocal fremitus and dullness over the middle of the right lung, from the vertebral border of the right scapula to the anterior axillary line. Breath sounds were absent; there were a few subcrepitant râles after coughing, and also bronchophony and whispering pectoriloquy. In contrast with the slight physical signs the morning temperature was 101°F., rising at night to 103°. The pulse was rapid, there was no cyanosis or dyspnoea, but the frequent severe cough increased the pain. The sputum was muco-purulent and tinged with blood, copious, odourless, and full of pneumococci. Radioscopy showed a central round cavity in the right lung, which changed its shape on coughing; it was half filled with fluid. About twelve days previously there had been a sudden rigor, followed by fever and sweating, dyspnoea, cough, and intense pain in the middle of the right lung. After four days the symptoms were slightly worse; the temperature remained between 100° and 101.4°. In ten days the sputum became muco-purulent, blood-tinged, and more abundant; in twelve days the patient had lost 6 kilograms. The temperature fell by lysis, and twenty-five days after admission the cavity had disappeared, leaving a slightly darker shadow at its former site. Six months later the patient was in good health, and the only sign of the lesion was a slight roughness of inspiration. In a second case, a boy aged 17 was attacked with cough, fever, vomiting, and diarrhoea. He improved and returned to work though asthenic. Three weeks later he had slight rigors, headache, pain at the right base, profuse sweating, and dyspnoea; his temperature was 104° and his pulse 108. His general state suggested enteric fever, but the Widal test was negative. The sputum was scanty, gelatinous, and muco-purulent; it contained numerous Gram-positive cocci. The temperature fell slightly, but no crisis occurred, and the whole of the right side of the chest was painful, especially at the base. On the left side over a small persistent area at the left scapular spine there were subcrepitant râles. The symptoms now resembled those of influenzal bronchopneumonia. There was scanty greenish muco-purulent sputum, containing Gram-positive diplococci and staphylococci. All abnormal physical signs in the left lung cleared up, but dullness persisted at the right base. The sputum increased in quantity and yielded a pure culture of *Staphylococcus aureus*. Signs of excavation were discovered in the right infraspinous fossa, and the general condition showed some improvement. Radioscopy showed a small cavity partially filled with fluid in the centre of the right lung, with complete diaphragmatic immobility on that side. An autogenous vaccine was injected daily for four days, causing a sharp febrile reaction and increasing the quantity of sputum. The dose was increased, and though the sputum was still very profuse the general condition improved notably. The physical signs diminished and the cavity closed, leaving a shadow in the skiagram the size of a bean. Three months after the initial attack the patient was discharged cured. The authors have been unable to find any record of a staphylococcal pulmonary abscess, and observe that visceral staphylococcal abscesses are usually secondary to a bony or skin invasion. They call attention to the rapid recovery under vaccinotherapy after the failure of ordinary treatment, and without surgical intervention.

388. Enteritis caused by B. paratyphosus B.

P. DELANOE and A. PAOLETTI (*Arch. de l'Institut. Pasteur d'Algerie*, December, 1926, p. 575) report a case of *B. paratyphosus* B infection in which a married woman was suddenly taken ill during the night after a meal of sausages. The chief symptoms were intense vomiting and profuse diarrhoea, the stools being semi-liquid, green, and fetid. The conjunctivae were discoloured and the tongue coated. Treatment consisted in dieting and the administration of calomel, followed by small doses of soda, urotropine, and benzonaphthol. The attack lasted about a month. After partaking of the same food the husband suffered from a similar attack, which, in his case, lasted only three days. Bacteriological examination of the faeces of the female patient produced an almost pure culture of *B. paratyphosus* B to the exclusion of *B. coli*, a point to which the authors draw attention. Repeated examinations of the faeces proved that this patient developed into a carrier of *B. paratyphosus* B, thus confirming the difficulty of eliminating these organisms from the intestinal tract.

Surgery.

389. Pelvic Sarcoma diagnosed as Appendicular Abscess.

A. LURJE (*Zentralbl. f. Chir.*, February 5th, 1927, p. 337) refers to Silberberg's record of the faulty diagnosis of appendix abscess as a malignant tumour, and reports a case in which the opposite diagnostic error was made. A girl, aged 14, had complained of severe pain in the right hip for five weeks; it later extended to the right iliac fossa, and the temperature rose to 102°. On the inner side of the right anterior superior iliac spine a definite swelling, covered by normal skin, was visible; it was dull on percussion, distinctly palpable, and appeared to rise from the deeper part of the iliac fossa. It was as large as a fist, very tender, globular, smooth, with definite induration, which on passive flexion of the hip became less. The abdominal wall was tense in this region. Extension produced lordosis and increased the pain; rotation was limited. No glands could be felt, the vertebral column was normal, and adnexal disease was excluded; on account of the fever it was regarded as an inflammatory infiltration with central suppuration of appendicular origin. On dividing the transversalis a spongy mass of sarcomatous tissue appeared which did not communicate with the peritoneal cavity; the operation was abandoned. A skiagram taken subsequently showed a shadow in the right iliac fossa and indefinite atrophy of the ileum. The patient died ten days later. At the necropsy there was found a well defined tumour covered by peritoneum arising from the middle of the right iliac fossa; it originated

in the iliacus and was unconnected with the subjacent bone. The greater part of the tumour consisted of chronic inflammatory tissue; in places there was some fibrino-purulent exudate, and elsewhere fibrous changes, resembling interstitial fibrous myositis. At the periphery there were ill-defined and very vascular masses of round cells of typically sarcomatous appearance.

370. True Adenoma Sebaceum.

V. PETTINARI (*Arch. Ital. di Chir.*, November, 1926, p. 693), who records an illustrative case in a man aged 26, states that there is an adenoma, properly so-called, of the sebaceous glands corresponding with the type described by Porta in 1859. It is a rare condition and must not be confused with the "adenoma sebaceum" of the Pringle and Balzer type, nor with the epithelioma adenoides cysticum of Brooke. It is quite distinct clinically from rhinophyma. The condition appears in the form of a nodule, which is usually single and varies in size from that of a pea to a large hen's egg; it is found in a situation full of sebaceous glands, such as the nose—as in Pettinari's case—scalp, or back. It always has a poor vascular supply, is sometimes ulcerated, and is usually adherent to the skin, but can be isolated from the surrounding tissues, and is of a fleshy and pasty consistency. It may appear at any age, but congenital or hereditary forms are not known. Most of the cases occur in males late in life. The course is benign, the growth slow, and the glands are not involved; recurrence, however, may take place after removal. Histologically the tumour is characterized by a new growth and hypertrophy of the sebaceous glands. It can be distinguished from a malignant growth by the strict limitation of the glandular acini, the morphological character of the cells, and the sharp separation from healthy tissues. Surgical removal is the only effective and rational treatment, and this was successfully performed in Pettinari's case.

371. Melanoma of the Toe.

A. CHAUVENET and MLLE E. DUBREUILH (*Bull. et Mém. Soc. Nat. de Chir.*, February 12th, 1927, p. 143) report a case of melanotic carcinoma of the little toe, in a man aged 48, who came for treatment on account of an ulcerated tumour of the toe which had grown slowly and was painless. The condition was diagnosed as a melanoma and high amputation advised. This was refused and the foot was removed by a Syme's operation in December, 1925. There was an apparent recovery following operation, but two months later the patient returned with oedema of the limb, ascites, and pleural effusion, and died in February, 1926, from recurrence of the disease. Melanoma of the nail-bed was described by Jonathan Hutchinson in 1856, and termed "melanotic whitlow." This tumour is more often found in the upper limb than in the leg. At first it may start as a black patch, and is taken for an ecchymosis; ulceration follows later, and the tumour may be black or red. When ulceration occurs the progress of the disease is usually rapid and it then becomes painful. The glands may be enlarged at any period of its growth, and they are often more pigmented than the primary tumour. The spread by the lymphatics occurs as in epithelial tumours, and in this respect it differs from sarcoma, which spreads by the blood stream. This tumour is commonly seen in those about 50 years of age, and is more frequent in females than in males. Trauma appears to be a definite predisposing factor. These growths have been regarded as sarcomata in the past, but appear really to have the structure of naevo-carcinomata, and arise in the epidermis.

Therapeutics.

372. The Action of Caffeine.

GROSSMANN and LUSICKY having reported that the caffeine portion of such double salts as caffeine-sodium-benzoate has no action on the central nervous system, pulse rate, or blood pressure, R. DREIKURS (*Wien. klin. Woch.*, February 3rd, 1927, p. 156) investigated the effects of injections of 0.4 gram of caffeine-sodium-benzoate, alone and in conjunction with atropine, on the pulse rate and blood pressure of 25 patients without demonstrable organic disease at a Vienna psychiatric-neurological clinic. He found that the response to the drug was fairly constant for each individual, but varied considerably from case to case, producing in some a slowing of pulse rate from 94 to 72 with lowering of blood pressure from 110 to 95 mm., while in others the pulse rate was unaffected or even increased, the blood pressure remaining unaltered or being raised, control injections of saline having in each case no effect. He reviews the literature and discusses the variations in his own observations, the discrepancies found in the results of other workers, and the fact that caffeine occasionally has a soporific effect, especially in persons in whom it produces marked bradycardia and lowering of blood pressure. He suggests as an explanation of these phenomena that hypodermic injections of 0.4 gram of caffeine-sodium-benzoate normally produce mild stimulation of the vagus. In certain individuals this may be marked, feeble, or absent, while in others the same dose produces stimulation of the sympathetic, the effect of the caffeine apparently depending on the comparative irritability (tone) of the vagus and sympathetic, as shown experimentally by means of atropine injections. The author's results indicate that the temporary preponderance of the vagus or the sympathetic which has been demonstrated by many workers may remain constant for a considerable length of time.

373. X-Ray Treatment of Erysipelas.

E. S. PLATOU and L. RIGLER (*Arch. Intern. Med.*, November, 1926, p. 573) remark that erysipelas is a striking example of those diseases in which the multiplicity and variability in the methods of treatment indicate an uncertainty as to the value of therapeutical procedures. It is obvious that, as erysipelas is a self-limited disease, any form of treatment to be judged effective must be so in a very prompt and definite manner. The authors record the results of *x*-ray treatment of 23 cases, with 18 cases as controls, in which the usual routine procedure of iced magnesium sulphite and glycerin packs was employed. Only one dose of *x* rays was given, and most patients had no other form of treatment except analgesics and sedatives, with the result that rapid improvement occurred in both the local and systemic manifestations, with a fall of the temperature to normal in one to two days. The duration of the disease from the time of *x*-ray treatment to clinical cure was from two to five days, with an average of three days in the irradiated cases; whereas in the controls the disease lasted from four to twenty-one days, with an average of more than nine days. Four of the control cases were fatal, while only one death occurred among the cases treated by *x* rays, in a patient suffering from measles bronchopneumonia complicated by erysipelas. No deleterious effects of the irradiation on the skin or hair were observed.

374. Antitoxin Treatment of Scarlet Fever.

W. T. BENSON and D. P. MACIVER (*Edin. Med. Journ.*, December, 1926, p. 701) record their observations on 107 cases of scarlatina simplex treated with intramuscular injections of concentrated scarlet fever antitoxin, with 107 control cases. Symptoms of serum disease appeared in 34 patients from four to fourteen days after the injection. In 28 cases a rash was observed, mostly urticarial, which persisted several days in the more severe cases. Other symptoms were rise of temperature, adenitis, and fleeting joint pains. The authors' conclusions are as follows: (1) Administration of antitoxin within the first forty-eight hours of the disease has a very favourable influence on the specific toxaemia of scarlet fever. In relieving the more urgent symptoms of the acute stage it undoubtedly renders the patient more comfortable. (2) There are indications that the liability to subsequent complications is diminished. (3) Administration of serum, even on the first day of illness, is not an absolute safeguard against the development of septic complications in convalescence. (4) In toxic scarlet fever serum should be given intravenously or intramuscularly as soon as possible and repeated when necessary.

375. Sodium Nucleinate in Pneumonia.

L. E. MILLER (*South African Med. Record*, December 11th, 1926, p. 531) refers to Gardner-Medwin's article in the BRITISH MEDICAL JOURNAL (1924, vol. ii, p. 49), in which it is shown that injections of sodium nucleinate increase the number of polymorphonuclears in the blood and the opsonic power, with beneficial effects in such diseases as influenza and pneumonia. Miller has now used the treatment for 117 natives, of whom 87 had lobar pneumonia and 30 bronchopneumonia. In 51 of the cases of lobar pneumonia the temperature fell by crisis; in 24 the crisis occurred on the second day after injection, and in 18 on the third day. In 16 other cases the temperature fell by lysis, and of the remaining 20 cases 13 appeared to be unbenefited, 7 terminating fatally. In the 30 cases of bronchopneumonia crisis occurred in 10, lysis in 10, and in the remaining 10 there was no response to treatment, and 4 deaths occurred. The case mortality of the treatment was thus 8 per cent. for lobar pneumonia, and 13.3 per cent. for bronchopneumonia. Miller finds that the intramuscular injection of 0.1 gram of sodium nucleinate is not too high a dose and usually brings down the temperature in forty-eight hours, otherwise the dose is repeated. Sodium bicarbonate is also given by the mouth, in half-drachm doses every four hours in severe cases, when the urine contains acetone. In a few cases profuse sweating occurred about two or three hours after the injection, and in six cases there was a false crisis about twelve to eighteen hours after injection. Miller believes that this treatment, though requiring further investigation, is of definite assistance in terminating lobar pneumonia quickly and successfully.

Anaesthetics.

376. Spinal Anaesthesia in Intestinal Obstruction.

P. DUVAL (*Bull. et Mém. Soc. Nat. de Chir.*, February 19th, 1927, p. 169) discusses two cases of acute intestinal obstruction, reported by A. CHENUT and J. QUÉNU, in which spinal anaesthesia brought about an immediate evacuation of the bowels. Duval has been able to collect a further series of twenty-two cases of a similar nature. It appears that in certain cases of intestinal obstruction—more particularly in cases of post-operative ileus—spinal anaesthesia is a most efficacious form of treatment. It has also proved successful in certain cases of mechanical ileus. The evacuations have been so complete in some of the cases that the condition has been cured. The question, however, arises in others as to what further treatment should be adopted. This depends on the real cause of the condition, and where this is mechanical further measures will, of course, be necessary. The effect of the relief of the obstruction, however, completely transforms the condition of the abdomen and allows exploration to be performed under excellent conditions. The abdomen instead of being distended is flat and relaxed, and the gut also is collapsed and easy to manipulate. The conditions and prognosis are completely changed by this procedure. This form of treatment may render an enterostomy unnecessary, specially in cases due to carcinoma of the bowel. The mechanism whereby this acts probably depends on the fact that the ileus is produced by stimulation of the peripheral nerves of the intestine which act on the centre in the medulla. The effect of the spinal anaesthetic is to suppress the inhibitory impulses, and this brings about active peristalsis owing to the free action of the excitatory nerves. This corresponds with the results obtained in certain animal experiments that have been carried out.

377. Spinal Anaesthesia in Urological Surgery.

M. F. CAMPBELL (*Brit. Journ. Anaesth.*, January, 1927, p. 162) records the results of spinal anaesthesia in 536 operative procedures in the urological department of the Bellevue Hospital, New York. It is regarded as the ideal anaesthetic for urological surgery, most of the patients having diseases of the kidneys, with advanced renal damage in many. Cases with hypertension are said to be especially suitable. Nephrectomies cannot yet be painlessly performed under spinal anaesthesia, since the pain of clamping the pedicle is not eliminated, but by the use of the double or "split" spinal anaesthesia satisfactory results are obtained in bladder work and suprapubic prostatectomy. Before the operation patients should be given a liberal amount of fluid, 1/4 grain of morphine, and 1/150 grain of atropine hypodermically. With the patient upright or prone local anaesthesia through the dura is used, and the injection is generally made in the third lumbar space, the average dose being 80 mg. novocain crystals dissolved in about 3 c.cm. of spinal fluid slowly withdrawn for the purpose and then reinjected. For the double or "split" spinal anaesthesia the injection is made in the twelfth dorsal and in the third lumbar spaces, the lower injection blocking at the point of their emergence those fibres which were centrally located in the cord at the site of the upper injection. While patients with hypertension do well under spinal anaesthesia, even though suffering from grave cardio-nephropathies, its use is said to be contraindicated in those with hypotension with a blood pressure below 100 mm. Other contraindications are extreme toxicosis, the moribund state, and the presence of spinal or brain tumours. A comparison of the mortality between general and spinal anaesthesia revealed a 4 per cent. difference in favour of the spinal. Campbell concludes that for operations below the diaphragm spinal anaesthesia is admirable, and is specially indicated in the presence of renal impairment.

378. Anaesthetization of Cardiac Cases.

H. K. DIMLICH (*Anesthesia and Analgesia*, February, 1927, p. 35) states that heart lesions in patients whose compensation is good do not contraindicate the use of nitrous oxide and oxygen, and that this method of inducing anaesthesia will give the best results in cardiac and other poor surgical risks when combined with preliminary injection of magnesium sulphate, morphine, and novocain one and a half hours before operation. The blood pressure is estimated after three-quarters of an hour, and another similar injection is given if the patient seems to require it. This is equivalent to the usual 1/4 grain of morphine, and is usually sufficient, though occasionally a larger dose may be deemed advisable. The patient is then encouraged to sleep, carried to the operating room, and anaesthetized with nitrous oxide and oxygen. A smaller amount of the anaesthetic than usual is often adequate, but occasionally ether may be required; these cases are exceptional, and the amount of ether employed is so small as to have no bad effect. Dimlich has found that in this way the excitement stage during induction is absent or only slight, greater relaxation is obtained, and no deleterious effects result. There is a marked reduction in the pain when consciousness returns, and morphine is less early required to relieve it. Careful examination of the heart, blood pressure, and kidney function before the operation is important.

379. Effect of Ethylene Anaesthesia on the Coagulability of the Blood.

D. C. STRAUS and H. H. RUBIN (*Journ. Amer. Med. Assoc.*, January, 1927, p. 310) have investigated the tendency to increased haemorrhage which occurs in operations performed under ethylene anaesthesia. In a series of twenty-five patients so anaesthetized the coagulation time was determined immediately prior to operation, during it, and on the following day, Bogg's modification of the Russel-Brodie coagulometer being used. In 20 cases the coagulation time was shortened during the administration of the anaesthetic and a further drop was noted at the end of anaesthesia. In four cases the coagulation time was not diminished until after the operation, and in one case the time was increased. The authors think the cause of the shortening of the coagulation time is the direct effect of the gas on the red blood cells, leading to agglutination and coagulation with the formation of fibrin. Other possible explanations relate to changes in the blood pressure or to increase in the specific gravity of the blood.

Obstetrics and Gynaecology.

380. Treatment of Abortion.

W. H. MAXWELL (*Journ. Med. Assoc. S. Africa* (*B.M.A.*), January 22nd, 1927, p. 40) in apyrexial cases of incomplete abortion advocates early evacuation of the uterus as being simple, safe, and avoiding the risk of haemorrhage and infection. He prefers the laminaria "tent," since Hegar's dilators may cause serious damage. Tents can be kept aseptic indefinitely in absolute alcohol and ready for use, and a slow, steady, and uniform dilatation is secured without any danger of laceration. The advantage of this method of dilatation is said to be most apparent in cases of about four months, and it is a great advantage to be able to explore the uterus with the finger. The use of the curette is only necessary when a piece of placenta is too firmly adherent to be removed by the finger. In febrile cases of sapraemia or septic intoxication rapid improvement follows the emptying of the uterus under an anaesthetic. In septicaemia caused by injury to the wall, cervix, or vaginal fornix Maxwell recommends dilatation and digital exploration, with removal of the septic contents, gentle douching, and avoidance of the unnecessary and dangerous curette.

381. Primary Carcinoma of the Fallopian Tube.

J. H. ENGELKENS (*Nederl. Tijdschr. v. Geneesk.*, January 22nd, 1927, p. 470), who records an illustrative case, states that, though secondary carcinoma of the Fallopian tube is frequent, usually following carcinoma of the uterus, a primary growth is very rare. So experienced a gynaecologist as Treub had never seen an example. Kehrer in 1908 collected 80 cases, of which only one was diagnosed before operation. In almost all the cases on record mention is made of a light yellow amber coloured discharge which is sometimes tinged with blood, or slightly pink. Le Dentu and Delbet draw attention to the occurrence of intermittent tubal crises, accompanied by violent pain in the lower part of the abdomen and by swelling of the tubes, which suddenly disappear after discharge of a watery or blood-stained fluid. As regards the etiology, as little can be said of cancer of the Fallopian tube as of cancers of other parts. All writers, however, mention a concomitant or pre-existing infection of the tube whereby the ostium abdominale is closed. The prognosis is generally bad, as tubal cancer rapidly gives rise to metastases. Successful treatment, as in all other cancers, depends on early diagnosis. Engelkens's patient was an unmarried woman, aged 60, who had had a watery vaginal discharge for about six months. She had never had any real pain, but only a feeling of discomfort in the lower part of the abdomen. On laparotomy the uterus was found to be enlarged and anteflexed, and the left tube showed a club-shaped swelling on its lateral aspect. Metastases were also found in the vesico-uterine fold and great omentum. The whole of the uterus with the adnexa and portion of the great omentum was removed. Subsequent recovery was uneventful. Histological examination showed that the growth was an aveolar carcinoma.

382. Gynaecological Complications of Appendicitis.

ACCORDING to SELLHEIM (*Zentralbl. f. Chir.*, February 12th, 1927, p. 386) while it is not uncommon for inflammation of the appendix to extend to the adnexa and set up such a condition as salpingitis, extension of adnexal disease to the appendix occurs less frequently. Many years ago he found that in appendicitis in women there is a definite inflammatory thickening of the right utero-sacral ligament. On rectal examination in a normal case, it will be found that the utero-sacral ligaments form only slightly perceptible ridges on either side of the pouch of Douglas; these ligaments are of great clinical importance as indicators of inflammation of the female genital organs. They are bilaterally thickened in endometritis, vaginitis, cystitis, proctitis, and peritonitis. Though the inflammatory process begins in the utero-sacral ligament, it frequently extends to the base of the broad ligament; also a slight degree of parametritis may be present. Sellheim states that twenty years' experience has shown him that unilateral inflammatory thickening of the right utero-sacral ligament is pathognomonic of appendicitis, when puerperal and gonorrhoeal inflammatory processes have been excluded.

383. Axial Torsion of the Fibromatous Uterus.

A. CHAUVENET (*Journ. de Méd. de Bordeaux et du Sud-Ouest*, February 10th, 1927, p. 106) describes a case of axial torsion of the fibromatous uterus in a married woman, aged 35, and states that 89 previous cases have been recorded. The patient had had two normal confinements, and had always been healthy, except for an attack of appendicitis, for which an operation had been performed. Two months after a slight and transient attack of pelvic pain she had a sudden violent paroxysm of pain; when seated the pain ceased, but it recurred on the slightest movement. The bowels acted normally and the patient slept that night, until awakened by recurrence of pain, which caused her to faint. On the following day she felt sick and could not pass flatus. A tumour in the right iliac fossa was thought to be an ovarian cyst with twisted pedicle. The patient's general condition was good. There was no fever and no abdominal distension, but some tenderness on palpation in the hypogastric and right iliac regions: in the latter a hard, tender, and slightly mobile tumour as large as two fists was felt. Bimanually the uterus was found to be abnormally high and displaced towards the right; it was surmounted by a hard mass which was separated from the uterine body by a groove. On opening the peritoneum a small quantity of blood-stained fluid escaped. The fibromatous uterus was found to be rotated axially from left to right through 180 degrees, so that the left ovary was on the right side and the right ovary on the left side. The torsion was easily corrected. The left ovary appeared to be healthy, but the right ovary was of a deep violet colour, cystic, and contained some ecchymoses. There was cervical oedema, and two small fibromata of the isthmus were present. Subtotal hysterectomy, with preservation of the left ovary, was performed. A large single interstitial fibroma occupied the posterior aspect and fundus of the uterus. Chauvenet adds that when torsion through 180 degrees occurs it is evident that tension on either round ligament must direct the fundus into the corresponding iliac fossa rather than into the lateral pouch of Douglas. He believes that this sign in certain cases may permit a diagnosis of uterine torsion to be made before operation.

Pathology.

384. Atypical Forms of the Tubercle Bacillus.

WHILE investigating leprosy, J. REENSTIERNA (*Arch. de l'Instit. Pasteur de Tunis*, December, 1926, p. 309) found that in one of his cultures, taken from a leproma of a tuberculous leper, bacilli appeared which after a time lost their acid-resisting properties and assumed the form of granular rods similar to *B. leprae*, or of small diplococci or streptococci. All the forms were Gram-positive, though they did not retain the Ziehl-Neelsen stain. In two cultures of Gram-positive, non-acid-resisting streptococci isolated from the blood of the same patient, acid-resisting bacilli of typical *leprae* form spontaneously appeared. The possibility of contamination was excluded, and the worker concluded, after experiments on monkeys, that both acid-resisting and non-acid-resisting forms of *B. leprae* do exist, and that this bacillus is a fragmentary form of a fungus. The close relation between the bacilli of leprosy and tuberculosis led Reenstierna to pursue further experiments on the latter. Working with an oidium, he found that after seven days' growth on bouillon glycerin, acid-fast bacilli, showing all the characteristics of tubercle bacilli, suddenly appeared among the buds and mycelia of the fungus, and in other cultures cocci were seen. Serums of rabbits, prepared by injections of different strains of these cocci, showed agglutination and complement fixation with the serums of individuals suffering from pulmonary tuberculosis, and not with those of the controls. The author maintains that these cocci are granules of tubercle bacilli (granules of Much), and that the bacilli themselves exist in both acid-fast and non-acid-resisting forms. He draws attention to the very small forms that traverse the placenta in congenital tuberculosis, and to different types of cutaneous tuberculosis in which bacilli seem to be absent.

385. A Modification of the Meinicke Test.

L. FEUERSTEIN (*Wien. klin. Woch.*, January 27th, 1927, p. 122) describes a modification of the Meinicke test for syphilis which has been employed at the Innsbruck Children's Clinic for more than two years in 600 cases. A drop of blood is drawn into a capillary glass tube 10 or 11 cm. in length and 0.2 to 0.7 mm. in diameter. When the blood is within 2 cm. of the distal end of the tube this is withdrawn from the skin and the distal end fused in a flame, the other end being left open, or it may be sealed with vaseline. In fifteen minutes the clot is extracted easily from the open end, and the capillary tube is then centrifuged for fifteen to thirty minutes. Into a small test tube is poured 0.1 c.cm. of Meinicke's antigen, which is a mixture of extract of horse heart with cholesterin, and 1 c.cm. of a 3 per cent. sodium chloride solution is poured into another similar tube. Both are then placed in a water bath at a temperature of 43° to 46° C. for ten minutes. On a glass slide 1 part of the patient's clear serum is mixed with 5 parts of the mixed contents of the two tubes; a coverslip is applied and ringed with vaseline to prevent evaporation. The slide is left at room temperature for one or two hours and then examined microscopically for flocculation on a dark stage, and again in six or eight hours. Feuerstein's results generally correspond with those of the Wassermann test; he finds this procedure very sensitive and of great value in quickly confirming a diagnosis of syphilis.

386. Glucose Distribution in the Blood.

R. EGE and KAREN M. HANSEN (*Acta Med. Scand.*, January 26th, 1927, p. 279) state that while glucose is only found in the plasma of animals, it occurs in both the red corpuscles and plasma in man. Mason, Ege, and Hagedorn have previously shown that the amount of sugar associated with the blood corpuscles was rather lower than the plasma-glucose concentration, and there was postulated a simple tension equilibrium between the two. The membrane of the blood corpuscles of man must be permeable for glucose. Osmotic experiments, however, proved the case to be more complex, and Ege then suggested that glucose was both combined (adsorbed) with the surface of the blood corpuscles and dissolved in a free state in their water content. The present authors conclude, as the result of experimental work, that glucose occurs in equal concentrations in the blood corpuscles and plasma of normal fasting individuals, but that in the corpuscles there is a considerable quantity of reducing substance (combined sugar) which is not given up instantly to an outer liquid with a lower sugar tension, and that the distribution of glucose between the plasma and red blood corpuscles in man cannot therefore be explained on the grounds of a simple distribution of glucose in a free dissolved form between the fluid of the plasma and of the red corpuscles.

387. Serology of the Bacillus of Whooping-cough.

M. KRISTENSEN (*C. R. Soc. de Biologie*, February 11th, 1927, p. 355) has found that the various strains of *B. pertussis* isolated in Denmark appear to be remarkably homogeneous, resembling eac[illegible] growth, their cultural reactio[illegible] In America, however, Krun[illegible] sch observed two different serological types of the bacillus. While accepting their results Kristensen regards it as possible that the serological variation originated during subculture in the laboratory and not in the human body. He argued that if there were really two serological types then there should also be two different antibodies demonstrable in the blood serum of the patients. To ascertain whether two types were actually present in patients suffering from whooping-cough he collected ten strains from patients situated in five separate areas of Copenhagen, together with the blood serum of the same patients. Each serum was tested against every organism, and all the strains reacted in the same manner, there being no indication of difference between them. Absorption tests were made with eight of the serums and eight of the strains, each serum being absorbed with each strain. In every test the agglutinins were completely absorbed. These observations, though made on a small scale, confirm his previous findings, and lead him to conclude that in Denmark there is only one serological type of *B. pertussis*.

EPITOME OF CURRENT MEDICAL LITERATURE.

Medicine.

388. **Neo-Natal Meningitis.**

DORA KARPLUS (*Wien. klin. Woch.*, February 24th, 1927, p. 250) concludes that the diagnosis of meningitis during the first month of life presents special difficulties and depends on the examination of cerebro-spinal fluid obtained by lumbar puncture. The sutures and fontanelles readily yield to moderate increase in intracranial pressure at this age, and meningeal signs and symptoms may be vague and limited to somnolence, increased or diminished irritability, and staring facial expression, while head retraction, abnormal reflexes, and pyrexia may all be absent. The infecting organism probably reaches the meninges most frequently, especially in *B. coli* cases, by the blood stream from some septic focus such as the umbilicus, mouth, or skin. Direct spread may occur in spina bifida or from a suppurating otitis media. The incidence of the various organisms producing meningitis at this age differs greatly from later infancy and other age periods. No case of tuberculous meningitis in an infant under 3 months has been recorded; *B. coli*, on the other hand, accounts for a large proportion (30 per cent.) of the recorded cases of neo-natal meningitis, while this organism is extremely rare as a cause of meningitis in older individuals. Streptococcal and staphylococcal cases also occur comparatively frequently (32 per cent.), especially in spina bifida with or without operation. Meningococcal meningitis is rare during the first weeks of life and does not respond to serum treatment so well as in older children. In pneumococcal meningitis the prognosis is even worse, death occurring within a few days of the onset of the disease. Cases due to various other organisms, such as *B. lactis aerogenes* and *B. pyocyaneus*, have also been recorded. Some authorities suggest that the otitis media found in a number of cases at necropsy is due to infection from the bath water, either by way of the external auditory meatus or by the mouth and Eustachian tube. Karplus has stated, however, that otitis media is so frequently found at necropsy in young infants that it is not justifiable to assume, when both conditions are present, that the meningitis is directly due to the otitis media.

389. **Contagious Influenzal Hiccup.**

MATESCO (*Paris méd.*, February 26th, 1927, 211) records an outbreak of six cases of hiccup at the Rumanian Ministry of War in the course of twelve days (December 29th, 1924, to January 10th, 1925). The spasms of hiccup commenced suddenly, were very intense, and the intervals between each were very short. Some attacks were double (in inspiration and expiration) and others subintrant, giving rise to respiratory obstruction and general disturbance, including headache, congestion, and restlessness. There was no morbid condition in the other organs. None of the patients presented myoclonus, diplopia, strabismus, ptosis, pareses, hyperaesthesia, or somnolence, but all had nasopharyngeal catarrh with slight secretion containing streptococci, staphylococci, and in two cases small groups of Pfeiffer's cocco-bacilli. All showed erythema and congestion of the tonsils. Blood cultures were negative. Matesco regards the outbreak as a form of phrenic influenza which is frequent among overworked persons, or as a larval form of encephalitis.

390. **Obesity and Heart Disease.**

W. D. REID (*Amer. Heart Journ.*, February, 1927, p. 311) remarks that in cardiac disease obesity appears frequently to influence the heart unfavourably, though the explanations of this fact given hitherto are unconvincing. He denies that the heart can be injured by the additional work thrown upon it by the increase in body weight, and adds that obese persons are known to be more prone to diabetes, which in turn leads to early arterio-sclerosis. In cases of obesity the diet is usually too rich in carbohydrates, and lacks vitamins and calcium. It has been shown that digitoxin is inactive without calcium. In animals or human beings living on diets deficient in minerals and vitamins there is impairment of the skeletal musculature and presumably also of the heart muscle. The unhygienic mode of life of most obese persons affords a partial explanation of the unfavourable influence of obesity upon the heart. Furthermore, statistical evidence shows that the obese are prone to chronic hyperpiesia and diabetes; both of which lead to arterio-sclerotic degeneration. This may explain the more serious impairment of the heart in some cases of obesity, probably through the deposit of cholesterin esters in the connective tissue of the intima. When this is overloaded with lipoids it is asphyxiated by these cholesterin esters, which decompose into cholesterin and free fatty acids, depositing calcium phosphate of bony hardness. The richness and character of the blood plasma are essentially influenced by diet, and thus atheromatosis is favoured. Atheromatous deposits are prone to change into athero-sclerotic lesions after the age of 30. The author concludes that the term "fatty degeneration" is a misnomer; fat does not result from the breaking down of cell protein.

391. **Confusion States in Insulinism.**

ACCORDING to T. SJÖGREN and J. TILLGREN (*Acta Med. Scand.*, February 28th, 1927, p. 684) Fletcher and Campbell have found that, in overdosage with insulin when the blood sugar drops to 0.05–0.08 per cent., symptoms appear in the form of profuse sweatings, pallor, sometimes increased pulse rate, marked anxiety, disturbance of co-ordination in the extremities, vertigo, and diplopia. On still further reduction of the blood sugar sensory and motor aphasia, dysarthria, delirium, and collapse supervene. Toronto investigators attribute the disturbed respirations and convulsions in animals to the central effect of insulin on the medulla oblongata. Olmstedt and Logan, using decerebrated cats, found anoxaemia with the hypoglycaemia if the medulla oblongata was intact, and concluded that this anoxaemia was the determining factor in the convulsions. Larsson believes that molecular or ionic displacements in the brain cause the eclamptic fits elicited by salt elimination in nephrosis. Snapper has described a case of diabetes with hypoglycaemic attacks of insulinism occurring as confusion with subsequent amnesia of the confused state. The present authors state that sensitiveness to insulin varies considerably, and is particularly prominent in children, youthful diabetics, and progressive pulmonary tuberculosis. They report four cases in which insulinism took the form of attacks resembling epilepsy. In three of these cases there were no signs of an epileptic constitution nor any psychical disturbance. The fourth patient, a case of genuine epilepsy with diabetes, gave no definite evidence of the epileptic attack and subsequent semi-stuporous condition having been caused by insulin hypoglycaemia. The authors observe that the possibilities of diagnosing a latent epileptic state are unfortunately extremely limited, and that a positive result of the hyperventilation test (normal in all their patients) is obtained in no more than 40 per cent. of cases, and only in very favourable circumstances.

Surgery.

392. **Aneurysm of the Hepatic Artery.**

O. TENANI (*Il Policlinico*, Sez. Chir., February 15th, 1927, p. 92) reports the case of a soldier who was admitted into hospital with a history of an attack of severe colic and slight jaundice, diagnosed as gall-stone colic. The distended gall bladder was palpable, the liver was not enlarged, and there was no haemorrhage. An aneurysm of the hepatic artery was found closely adherent to the bile duct and vena porta; the gall bladder was much distended and full of grumous fluid. The aneurysmal sac was excised and the artery tied. The patient died a few days later from hepatic insufficiency. At the autopsy multiple foci of hepatic necrosis were seen, the biliary passages were full of bile, and a very small track between the aneurysmal sac and the ductus choledochus could be made out. There was no history of syphilis, but the patient had had an attack of typhoid fever. The author refers to the small number of cases hitherto described and discusses the difficulty of treatment. The common triad of symptoms is pain, jaundice, and haemorrhage.

393. **Treatment of Hernia by Living Sutures.**

B. L. COLEY and E. BURKE (*Amer. Journ. Surg.*, January, 1927, p. 1), considering the later methods of repair of hernia, describe a procedure adopted for the closure of large indirect and direct hernias. Fascial strips are taken from the opposite thigh by an assistant. The conjoined tendon and internal oblique muscle are approximated to Poupart's ligament with the continuous living suture precisely as in the ordinary overlapping operation. A second row of sutures is superimposed upon the first row. The medial leaf of the external oblique is then sutured to Poupart's ligament and the lateral leaf is overlapped. Thus at the end of the operation the cord lies subcutaneously. The patient lies during convalescence with the shoulders and knees raised to relieve tension on the

parts repaired. Wound infection has been the most serious complication after operation. Fifty patients have been treated, with six recurrences. Apart from wound infection the post-operative course does not differ from that in ordinary hernia. The authors add that the operation is valuable in post-operative ventral and large umbilical hernias. The cases treated offered poor prospects by any other method of treatment, and so the percentages of recurrence are somewhat misleading.

394. Epithelioma of the Lip.

W. M. SHEDDEN (*Boston Med. and Surg. Journ.*, February 17th, 1927, p. 262) gives statistics of the surgical treatment of 294 cases of epithelioma of the lip in the Massachusetts Hospital from 1909 to 1923. He describes a radical neck dissection employed, and states that cures lasting for three years were obtained in 76 per cent. of all cases so treated and in 42 per cent. of cases when the glands were infected. He states that metastatic cervical gland cancer can exist in the absence of palpable glands, but every palpable gland is not necessarily cancerous. As in all malignant disease, early diagnosis is most important, and something may be learned as to prognosis and choice of operation from classification of the relative pathological malignancy of the growths removed. The extent of neck dissection required is determined by the position of the growth on the lip. Syphilis is rarely present and does not contraindicate operation. There is little evidence of heredity.

395. Hydatid Disease in Childhood.

L. BACCARINI (*Arch. Ital. di Chir.*, December, 1926, p. 73) records five cases in children aged from 5 to 10 years, which were the only examples of hydatid disease met with among 30,401 children who attended the out-patient department of the surgical pediatric clinic of Florence University from 1909 to 1924. In the first case the hydatid cyst was found in the thyroid gland, in the second in the liver, in the third in the liver and right lung, in the fourth in the right lung, in which suppuration had taken place, and in the fifth in the neck. All these children came from the country, where there was greater likelihood of their coming into contact with animals suffering from hydatid disease. In all the cases the cysts were unilocular and showed no daughter cysts. In three the cyst was not of great size, but in two (those in which the liver was affected) the size was considerable. The symptoms and signs, however, were not marked, apart from some difficulty noticed in the first case due to pressure on the upper respiratory tract. Suppuration occurred in only one case. All made a good recovery after operation.

Therapeutics.

396. Novasurol as a Diuretic.

R. LINCIO (*Rev. Méd. de la Suisse Romande*, January 25th, 1927, p. 19) discusses the diuretic action of novasurol, which is a combination of veronal with a salt of mercury and sodium. It is often given with success when all other diuretics have failed, either intramuscularly or intravenously, the dose ranging from 0.5 to 2 c.cm. of a 10 per cent. aqueous solution. No toxic action on the kidneys has been observed following these doses; but the powerful diuretic action is only transient, though it may strengthen the action of other diuretics and cardiac tonics. Of twelve cases of acute or chronic nephritis treated with novasurol combined with ammonium chloride given by the mouth in daily doses of from 5 to 16 grams, diuresis was much increased in ten, in one case the treatment failed, while in another the ammonium chloride caused acidosis and the treatment was stopped. The value of novasurol in hepatic cirrhosis is doubted; some authors regard it as a direct liver poison, while others claim good results in ascites, which had previously resisted all other treatment. Lincio describes the successful treatment of cardiac failure, chronic glomerulonephritis, hepatic cirrhosis, and tuberculous pleurisy. He concludes, however, that it should be regarded as a last resort, only to be employed when other remedies have failed. Ammonium chloride increases the action of novasurol, and the action of both drugs is cumulative, so that after their discontinuance normal diuresis is maintained.

397. Banana Pulp in the Treatment of Marasmic Infants.

H. THURSFIELD (*Arch. Dis. in Childhood*, February, 1927, p. 49) records rapid improvement following the use of banana pulp in six infants—four of the true marasmic type, and two "ruminators." One patient, who was 3 months old, weighed 10 lb. on admission. At the end of ten weeks, on a diet of cow's milk, whey, and Benger's food, of a calorie value of 580 daily, he weighed less than on admission. About 300 calories were carbohydrate, 200 fat, and the remainder protein. The pulp of one ripe banana was then added to his diet. There was a gain in weight of 4 ounces in the next two days. In five days' time the diet consisted of cow's milk and the pulp of two bananas, with a calorie value of 590. Shortly after it was possible to increase the amount of milk, though previously such additions had always caused indigestion and loss of weight. The infant put on weight steadily, gaining 1½ lb. in three weeks, when he was discharged on a diet of about 700 calories, of which 100 were banana-carbohydrate calories. The banana pulp is prepared by peeling a ripe banana, removing bruises and obvious fibres, pulping the remainder with a fork, and straining it through coarse-meshed muslin. The resulting pulp is mixed with the milk in one or several feeds. The author cannot account for the remarkable improvement noted in all the cases of his series.

398. Datura Stramonium in Parkinsonism.

E. JUSTER (*Bull. Soc. de Thér.*, February 9th, 1927, p. 48), who first recommended datura stramonium for the treatment of Parkinsonism two years ago (see *Epitome*, March 27th, 1926, para. 346), states that though its action is usually very definite it persists only so long as the patient is under the influence of the drug. It should therefore be given every day. There is no fear of its prolonged use causing habituation. On the contrary, Juster has been able to diminish the dose, especially if large doses were given at the onset. Moreover, no toxic symptoms were observed provided the patient was not allowed to get constipated. If for any reason he developed gastro-intestinal disturbance, the datura was stopped for two or three days and then resumed in larger doses. In order to prevent the occurrence of secondary symptoms, such as dryness of the mouth and mydriasis, the datura was given two to six times a day in the form of suppositories, each containing 20 cg. of powdered stramonium leaves. Juster suggests the following tests for determining the degree of Parkinsonism rigidity: (1) There is an apparent shortening of the affected arm when both arms are extended parallel; (2) forced pronation or supination is difficult in the rigid arm; (3) there is great variability in the suppleness and stiffness of the movements when the joint is passively moved a certain number of times (thirty to fifty); (4) there is a diminution or complete absence of the ability to swing a stick, the patient carrying it like a candle. These tests render it possible to estimate the degree of rigidity which responds to the action of stramonium.

399. Malarial Treatment of Leukaemia.

T. LUCCHERINI (*Il Policlinico*, Sez. Med., February 27th, 1927, p. 60) reports four cases of leukaemia treated successfully by the artificial induction of malaria. He considers this treatment likely to be effective in the acute and subacute forms of leukaemia, in which types radiotherapy is useless. In chronic leukaemia, malaria therapy should not be used except where *x* rays have done no good; in such cases it may be tried experimentally.

400. Therapeutic Value of Reducing the Salt Intake.

P. SAXL (*Wien. klin. Woch.*, February 17th, 1927, p. 229) believes that a reduction in the use of sodium chloride is of value in a variety of conditions because the osmotic pressure of the body fluids is thereby altered; he advocates it particularly in all forms of more or less generalized oedema, cardiac, renal, or anaemic, though not in the purely local or inflammatory types. Since a reduction in the elimination of salt entails also a reduced excretion of water, the work of the kidneys is diminished. The intake of salt should therefore be strictly limited in acute and chronic nephritis, but there is no need to reduce the salt in the diet in focal nephritis if urine of normal concentration is being passed. A salt-free diet is also indicated in diabetes insipidus where polyuria is associated with some degree of salt retention, though there is no tendency to oedema, likewise in cases of arterio-sclerotic kidney, where in spite of polyuria and absence of oedema there is often a reduction in the salt excretion. Such dieting is also of value in acute endocarditis, in which salt retention may occur without evidence of gross renal damage. It is likewise useful as an adjuvant to other diuretic measures, especially the use of such diuretic drugs as digitalis, theobromine, caffeine, and novasurol, which all have a greater effect on the excretion of salt than on the output of water by the kidneys. It is now generally recognized that dehydration may be almost as readily effected by a salt-free diet as by the limitation of fluids; it has therefore been found useful in certain types of obesity in which there is marked retention of water in the tissues. In cases of high arterial tension salt restriction and limitation of fluids should only be tried when there is definite evidence of inefficient excretion. F. DONATH (*ibid.*, p. 230) describes in some detail the planning and preparation of diets with reduced salt content so as to be most palatable to the patient. He supplies a table of the chloride content of the commoner articles of food.

Dermatology.

401. Recurrent Erysipelas of the Legs.

I. L. MCGLASSON (*Arch. Derm. and Syph.*, December, 1926, p. 518) quotes statistics showing that while from 81 to 90 per cent. of all cases of erysipelas occur on the face, only 8 per cent. involve the legs. He records his observations on seventeen cases of recurrent erysipelas, sixteen of which occurred on the feet and legs, associated with dermatitis of the feet, and one on the hand, in a dentist the subject of novocain dermatitis, who had had eight attacks of erysipelas extending over a period of three years. The oldest patient in the series was a man, aged 74, who had had twenty or thirty attacks extending over a period of twelve years. The youngest man was aged 28. Treatment was unsatisfactory before the etiology of the dermatitis in the toes was known, but after the paper of Ormsby and Mitchell in 1916 it was possible, except in the case of novocain dermatitis, to find mycelia in practically every case, and treatment of the eczematoid ringworm resulted in arrest of the complaint.

402. Arsenical Dermatitis.

B. P. BANNERJI (*Indian Med. Gaz.*, February, 1927, p. 81) reports the case of a man with hard chancre on the prepuce and a history of syphilitic infection, to whom an initial dose of 0.3 gram of novarsenobillon was administered. This was followed by injections of 0.45 gram and 0.6 gram eight or ten days later respectively. As no improvement was shown 0.9 gram was given twelve days subsequently when a severe rigor set in with fever, acute headache, and nausea, the symptoms subsiding in twenty-four hours. The ulcer remaining unchanged, a fifth dose, of 0.9 gram, was given ten days after the preceding one. This time the reactionary symptoms were severer, and on the third day the patient developed intense jaundice with a maculo-papular rash over the whole body, very severe pain, and pruritus. Gradually the whole body became swollen, the mouth was full of aphthous patches, and continuous fever, nausea, vomiting, and anorexia developed. The case was clearly one of arsenical dermatitis, with symptoms of acute yellow atrophy of the liver. The treatment given was a saline mixture by the mouth, calamine lotion externally, absolute rest, and a regulated diet. Later a proprietary preparation, acnetox, was prescribed, and subsequently a general tonic. The patient made an uninterrupted recovery.

403. Dermatitis due to Celery.

LEGRAIN and BARTHE (*Bull. Soc. Française de Dermatol. et de Syph.*, November 18th, 1926, p. 662) report a case of dermatitis due to working with celery. A man, aged 30, ten days after picking celery presented a dermatitis limited to the forearm and hands; it was characterized by oedema and vivid red erythema, with some large-sized vesicles. The eruption was confined to the dorsal and lateral aspect of the hands, fingers, and forearm. The maximum display was on the index finger, thumb, and radial border of the forearm, which were the parts coming most into contact with the celery. Simple sedatives and abstention from work soon cured the rash, but it returned when he went back to his employment. The authors do not know of any other reported case of dermatitis due to celery.

404. Xanthoma Diabeticorum.

E. GOLDSTEIN and J. HARRIS (*Amer. Journ. Med. Sci.*, February, 1927, p. 195) report the occurrence of diabetic xanthoma showing a peculiar process of involution in a patient suffering from diabetes mellitus, to whom insulin was administered in the late stages of the disease. There was no history of any previous specific or serious illness, but three years previously the patient began to have symptoms of diabetes, and was put on a low carbohydrate regimen. One year after the onset of the initial symptoms small, discrete, yellowish nodules appeared on the extensor surfaces of both legs, and six months later similar nodules invaded both palms and elbows. After another six months he entered hospital and was placed on a diet of 1,200 calories and given 45 units of insulin daily. During the next three months there was a gradual improvement in the skin lesions, and he became sugar-free, marked glycosuria, however, returning. The blood plasma cholesterol never showed more than 306 mg. per 100 c.cm., and repeated Wassermann tests were negative. Histologically the nodules proved to be xanthoma with connective tissue proliferation. The authors state that there is a definite relationship between the type of nodule and the manner and rapidity of involution, the miliary disappearing much sooner than the lenticular form. In most cases the disappearance of glycosuria is accompanied by a marked improvement or a complete resolution of the lesions. The eruption, however, may disappear when diabetic symptoms are unchanged; and again, diminution of sugar may find the nodules unaltered or even worse. It has not been determined whether insulin has any effect on the xanthoma. Though xanthoma diabeticorum is characterized by a hypercholesterolaemia the level of blood cholesterol need bear no definite relation to the severity of the diabetes, the blood sugar, and the xanthoma lesions, and hypercholesterolaemia (an occasional symptom of diabetes) does not necessarily imply the presence of xanthoma. The consensus of opinion is that the xanthoma nodules vanish entirely on resolution, but the authors found in their case that, while the palmar lesions disappeared completely, those on the elbows coalesced and left large pigmented patches, and those on the legs and thigh underwent degenerative changes resulting in extensive scar formation.

Obstetrics and Gynaecology.

405. Whooping-cough at the End of Pregnancy.

K. GOLDSCHMIED (*Wien. klin. Woch.*, February 17th, 1927, p. 186), who reports a personal case, illustrates the infrequency of whooping-cough in adults by the fact that in Heubner's series of 187 cases there were only three adults. The occurrence of whooping-cough in pregnancy is so rare that Goldschmied has found only a few examples on record. According to Simpson, haemorrhage and abortion are not frequent even when whooping-cough occurs in the early months of pregnancy. Schott has published a case of hydrorrhoea due to the rupture of the membranes during violent attacks of coughing. In the puerperium pneumonia is likely to arise as a complication. Goldschmied's case occurred in a 2-para, aged 38, who contracted whooping-cough in the last month of pregnancy and gave birth to a healthy child one and a half weeks before the expected term. Delivery, which was accompanied by violent paroxysms of coughing, was somewhat precipitate. The child, who was kept away from the mother for five weeks, being fed on the pumped-off breast milk, did not contract the disease. Goldschmied adds that it is a mistake to suppose that whooping-cough does not occur in the newborn, as examples have been reported by Bouchut, Rilliet and Barthez, Cockayne, and John Phillips, among others.

406. Treatment of Complete Prolapse of the Uterus in Aged Women.

ACCORDING to L.-E. PHANEUF (*Bruxelles Méd.*, February 20th, 1927, p. 524) uterine prolapse in women past the menopause is generally treated by vaginal or vagino-abdominal operations. He prefers the former, and employs the Watkins-Schauta-Wertheim method, which consists in the interposition of the uterus into the vesico-vaginal septum in order to support the bladder, followed by amputation of the cervix when atrophy, ulcerations, or lacerations are present, and colpoperineorraphy. A curved sound is introduced into the bladder, and a transverse incision made through both the mucosa and aponeurosis. The bladder, separated from the vaginal septum (the mucosa and aponeurosis forming two layers, one on each side), is drawn towards the symphysis. The vesico-uterine peritoneum is opened, the uterus is drawn into the vagina, and its posterior surface sutured to the peritoneum. Four sutures are then inserted into the anterior uterine wall, the upper one at the level of the cornua and the lower one in the angle between the cervix and body, the others being placed at equal distances between these two. If the uterus is atrophied, Phaneuf practises vaginal hysterectomy. In all cases high colpoperineorraphy is performed, Douglas's pouch being also obliterated where there is a probability of the formation of an enterocele. The author cites 126 vaginal operations (111 by uterine interposition, 10 by vaginal hysterectomy, and 5 by the operation of Le Fort) with only 3 deaths, none of which were due to the operation. Phaneuf maintains that these uterine interposition operations involve less risk to the patient and less danger of recurrence. In debilitated patients, in whom a lengthy operation is contraindicated, he performs Le Fort's operation.

407. Pituitary Extract in Obstetrics.

W. GOSSET (*Therapeutic Gazette*, February 15th, 1927, p. 77) finds pituitary extract a most valuable drug in obstetrics, though it is dangerous in unskilled hands. He prefers pituitrin, and indicates the conditions in which it may be administered. He does not use it for the induction of labour, but he states that during the latter part of the first stage, in a slowly progressing tedious labour, where the relations of the head and pelvis are normal, the administration at intervals of 2 to 6 minims of pituitrin will increase the force of uterine contractions and thus shorten labour. Pituitrin is especially useful in the second stage of labour, doses of 2 to 4 minims often inducing the necessary contractions to complete delivery; but in the third stage of labour Gossett never

employs it. Pituitrin is indicated in prolonged labour, where the patient is becoming exhausted, where uterine contractions are getting weaker, and in uterine stasis with the head on the perineum. He adds that the following conditions must be present: normal relations of head and pelvis, engagement of the presenting part, fully or nearly fully dilated or dilatable os, and normal presentations. In marginal or partial placenta praevia with incomplete dilatation of the os and rupture of the membranes a small dose of pituitrin may be sufficient to force the presenting part down against the placenta and into the pelvis, the head thus acting as a very efficient tampon.

408. Idiopathic Menstrual Bleeding.

E. ALLEN, E. L. COMPERE, Jun., and W. C. AUSTIN (*Amer. Journ. Obstet. and Gynecol.*, February, 1927, p. 156) have tried parathyroid extract for the control of idiopathic menstrual bleeding. Collip had previously shown that injections of this extract raised the calcium content of the blood and increased the viscosity, and working on his lines the authors found that the best results were obtained in the treatment of idiopathic menstrual bleeding when the administration of the extract was spread over three or four days. They recommend a total amount of from 120 to 160 units, given in doses of 20 units morning and evening, the best results being obtained by starting the intramuscular injections the day before a period was due. Though the cases were too few to permit of definite conclusions being formed, the authors state that parathyroid extract appears to shorten the bleeding and clotting time of the blood, to reduce appreciably the length of the period and amount of blood lost, and to produce a feeling of greater strength, vitality, and energy during the intermenstrual periods.

Pathology.

409. Anaphylaxis and Asthma.

V. PENNATI and A. TOLOMEI (*Rif. Med.*, February 14th, 1927, p. 151) have investigated the proteins of asthma-producing substances with regard to their capacity for causing anaphylactic symptoms. The proteins employed were derived by alcoholic extraction from the pollen of *Poa pratensis* and *Brassica rapa*, and from the scurf of the horse, ox, and ass. The concentrations of the various extracts varied from 0.03 to a maximum of 10 per cent. Using rabbits as experimental animals, 5 c.cm. of the solutions were injected subcutaneously every six days, and after an interval of several days following the sixth or seventh injection, 2 to 4 c.cm. of the same solution was injected intravenously. The characteristic phenomenon of Arthus was taken as evidence of anaphylaxis. Control rabbits injected in a similar manner with normal horse serum gave typical anaphylactic reactions. The experiments showed that the proteins of epidermic derivatives and pollen of flowers which give rise to bronchial asthma are unable in the doses employed to cause the local anaphylactic phenomenon of Arthus in rabbits.

410. Preparation of Diphtheria Anatoxin.

ACCORDING to J. L. MONTEIRO (*Memorias do Inst. de Butantan*, 1926, p. 96) the attenuation of diphtheria toxin by its transformation into anatoxin on the addition of formalin varies according to the composition of the broth culture. He advocates the adoption of a uniform technique for preparing broth cultures for the production of toxin in various serum institutes. Anatoxin may be employed with advantage in the production of diphtheria antitoxin, with results closely resembling those obtained with pure toxin but in a shorter time and without any risk. It also indicates after four or five injections which animals are good and which are bad producers of antitoxin. For the production of antitoxin it seems best to employ a mixed method consisting in injection of four or five doses of anatoxin followed by pure toxin. In conclusion Monteiro maintains that, owing to its harmlessness and the rapid immunity which it induces, anatoxin is of undoubted value in antidiphtherial immunization, and should be used for this purpose as widely as possible.

411. Toxaemia in Scarlet Fever.

J. D. TRASK (*Journ. Clin. Invest.*, December 20th, 1926, p. 391) states that the skin test dose employed by the Dicks is that at present taken as the unit of toxin, the strength of other toxins being measured by it. In order to ascertain the degree of toxaemia in scarlet fever cases by determining the number of toxin units present in the circulating blood, this investigator tested the serums from twenty-five scarlet fever patients. The amount of toxin in the blood was estimated by determining the smallest quantity of serum which would give a positive reaction on intracutaneous injection; then by discovering the reactivity of the same individual to the standard filtrate toxin, the toxin content of the serum could be calculated in terms of standard units. The results showed that the amount of toxin in the blood during the acute stage of the disease varied between very wide limits; that the size and intensity of the local skin reaction caused by 0.3 c.cm. of serum from scarlet fever patients provides a rough but fairly satisfactory measure of the amount of toxin present; that clinical estimation of the degree of toxaemia is subject to considerable error; and that, owing to the difficulty in estimating the actual degree of toxaemia by clinical observation, a generous excess of antitoxin should be administered in the treatment of scarlet fever. F. G. BLAKE and J. D. TRASK (ibid., p. 397) find that the specific toxaemia of scarlet fever is a self-limited phase, and that its duration parallels that of the rash. The degree of toxaemia, while the rash is present, depends largely on the presence and severity of septic complications. When the rash has faded, the specific toxaemia is of low degree or has terminated, even though severe septic complications may continue.

412. The Toxins of Haemolytic Streptococci.

MARY B. KIRKBRIDE and MARY W. WHEELER (*Journ. of Immunol.*, January, 1927, p. 19) have compared the toxin production of strains of haemolytic streptococci isolated from cases of scarlet fever with that of strains from other sources. Of 109 strains isolated from typical cases of scarlet fever 99, or 90.82 per cent., produced potent toxins, while the remainder were non-toxic under the conditions used. Of 111 strains of haemolytic streptococci recovered from infections not diagnosed as scarlet fever 76, or 68.47 per cent., produced potent toxins. According to toxin-antitoxin neutralization tests on goats approximately 67 per cent. of the toxic strains from both sources produced toxins similar to those produced by the standard Dochez strain; the toxins of the remaining strains were not neutralized by an antitoxic goat serum produced against the Dochez strain. These results suggest that there may be important differences in the action of streptococcus toxins, and emphasize the difficulty that is so often encountered in distinguishing a specific group of scarlatinal streptococci from other haemolytic strains. Further tests made on human beings show that this difficulty is a very real one. Some filtrates from scarlatinal strains failed to elicit a skin reaction in persons who were susceptible to filtrates of the standard strain; at times they induced a reaction in persons who were insusceptible to the standard strain. Sometimes the filtrates were not neutralized by a standard antitoxin. Similar observations were made on strains of non-scarlatinal origin. The results obtained were in fact so irregular that the authors consider it impossible by means of toxin neutralization tests to distinguish between haemolytic streptococci of scarlatinal and non-scarlatinal origin.

413. The Prophylactic Action of Tellurium in Experimental Syphilis.

C. LEVADITI (*C. R. Soc. de Biologie*, March 11th, 1927, p. 585) has followed his demonstration of the therapeutic action of tellurium in experimental syphilis of the rabbit and in naturally acquired syphilis in human beings by an attempt to determine whether this drug has any preventive action. In his first series eight rabbits were injected with 0.025 to 0.095 gram of tellurium per kilo of body weight. From ten to twenty-seven days later they were infected with a syphilitic virus, a subscrotal graft being made. Six of these animals proved refractory; two developed syphilis. In his second series ten rabbits received 0.0363 to 0.1 gram of tellurium per kilo, and were inoculated with the virus eight days later. Only one animal developed syphilis; the other nine proved refractory. The author concludes that the administration of 0.025 to 0.1 gram of tellurium per kilo eight to twenty-seven days before infection exercises a very marked prophylactic action on the development of syphilis. To ascertain how long the state of resistance lasted he reinoculated fourteen of the rabbits with the virus 103 to 116 days after the injection of tellurium. Eight of the animals developed syphilis; the remainder again proved refractory. It would therefore appear that the prophylactic action of tellurium may remain in evidence for three or four months, though its action after this time is not so sure as at an earlier period. An endeavour was made by C. LEVADITI and Y. MANIN (ibid., p. 587) to find out why some rabbits remained refractory for three months or more after a single injection of tellurium, while others had again become susceptible. It was surmised that the prophylactic action depended on the quantity of tellurium remaining in the tissues. Analyses were therefore made to estimate quantitatively the distribution of the metal in the tissues of the two lots of rabbits. The results showed that in the refractory animals the quantity of tellurium, particularly in the kidneys, was much greater than in the rabbits that had become susceptible. It would appear that for prophylaxis a definite amount of the metal must be present in the tissues; a smaller quantity cannot prevent the growth of the syphilitic virus.

EPITOME OF CURRENT MEDICAL LITERATURE.

Medicine.

414. Desquamation following Measles.

A. REULAND (*Jahrb. f. Kinderheilk.*, February, 1927, p. 202), as the result of the examination of 70 cases of measles, came to the following conclusions. With very few exceptions desquamation occurs in every case of measles. It starts directly after the appearance of the eruption, the first signs developing between the second and fourth day from the outbreak of the rash. The desquamation usually lasts on the average seven to eight days; it seldom lasts less than four days, but often persists for more than eight days, though a duration of more than sixteen days is exceptional. In at least half the cases it is confined to the face, and is almost always found there first, the cheeks, circumoral region, labial commissures, forehead, chin, naso-labial folds, and above the nose being specially affected. Only certain parts of the rest of the body are involved, chiefly the back and sides of the trunk, and the extensor surfaces of the limbs. The hands and soles usually escape. The character of the desquamation is almost always branny. Scales of any size are rarely, if ever, seen. The degree of the desquamation does not always depend on that of the eruption, although intense desquamation occurs only after an intense rash, and a faint rash is usually followed by slight desquamation. The form and size of the individual scales are more or less affected by the degree of the papule formation. Artificial means of producing hyperaemia, such as hot baths and mustard packs, also favour desquamation.

415. Sudden Death in Enteric Fever.

J. JACOBI (*Med. Klinik*, March 4th, 1927, p. 316), who records an illustrative case, states that in a small proportion of cases sudden death may occur in enteric fever, mainly in convalescence and irrespective of the patient's age and constitution. The two principal causes of this occurrence are myocarditis and vasomotor paralysis on the one hand and pulmonary embolism on the other. Myocarditis usually develops in the second or third week of the disease, and early signs of circulatory weakness are to be attributed to vasomotor paresis. Inflammation of the heart muscle is recognized by the relative bradycardia of typhoid fever being replaced by tachycardia, an irregular and unequal pulse, dilatation of the heart, and the appearance of murmurs. Often, however, the cardiac inflammation which gives rise to sudden death is not manifested by any clinical signs. Both myocarditis and vaso-paresis are much more common in typhoid than in paratyphoid fever, in which such complications are rare, and occur only in severe forms. Pulmonary embolism may be due to thrombosis in a peripheral vein, or, less frequently, to cardiac thrombosis. Jacobi's patient was a girl, aged 17, who while recovering apparently from a paratyphoid B infection collapsed suddenly, became dyspnoeic, and died in a few minutes. The necropsy showed thrombosis in the left femoral vein and embolism of the main branches of the pulmonary arteries. The femoral thrombosis had not given rise to any symptoms during life.

416. Chronic Myelogenous Leukaemia.

M. C. RIDDLE and C. C. STURGIS (*Arch. Intern. Med.*, February 15th, 1927, p. 255) record the results of a statistical study of 257 determinations of the basal metabolic rate in chronic myelogenous leukaemia. In untreated cases the rate is, with few exceptions, characteristically raised, the degree of elevation depending in general upon the severity of the leukaemic process and thus being of value in indicating prognosis. Treatment with *x* rays usually produces a transitory rise in the rate which does not last more than three days, and in those benefited by the treatment this rapidly falls to normal for from three to six months. Patients in the last stages of the disease are unaffected by treatment and continue to have an elevated rate. A direct correlation exists between the pulse rate and the degree of elevation of the metabolism, showing an average increase in the basal pulse rate of 17 per cent. for each 10 per cent. rise in basal metabolism. No fixed relationship appears to exist between the basal metabolic rate and the degree of anaemia. The basal metabolism is frequently high with high white cell counts, and low with low counts; it is usually high when the percentage of young myeloid cells is great, and especially when their degree of immaturity is marked. Careful daily studies of five patients showed that the general level of the basal metabolic rate depends upon the degree of elevation of the total white blood cell count and of the percentage of immature myeloid cells. It is suggested that the increased rate of destruction of the white blood cells may be an important factor in causing the elevation of metabolism in the disease.

417. Meningococcal Purpura Fulminans.

S. BATTLEY (*Amer. Journ. Dis. Child.*, February, 1927, p. 244) reviews the literature and reports a case of this disease in a male infant aged 10 months, the total duration of the illness being twenty hours. Bluish-red blotches appeared on the skin, especially of the face and buttocks. Death was preceded by convulsions. The necropsy showed several small haemorrhages in the pleura and on the epicardium, and extensive haemorrhages into the suprarenals. Nothing abnormal was found in the brain except engorgement of the small vessels. Bacteriological examination showed intracellular and extracellular organisms resembling meningococci in sections of the various tissues. The case is an example of the frequent finding of haemorrhage into the suprarenals in rapidly fatal cases, which, according to some authors, is probably the cause of death. It also illustrates the presence of meningococcic septicaemia without the development of meningitis.

418. The Effect of Bronchial Asthma on the Heart.

H. L. ALEXANDER, D. LUTEN, and W. B. KOUNTZ (*Journ. Amer. Med. Assoc.*, March 19th, 1927, p. 882), as the result of the study of fifty patients who had suffered from bronchial asthma for not less than five consecutive years, have come to the conclusion that, as a rule, the heart remains singularly free from injury in such cases, in spite of the attendant emphysema. In three cases definite cardiac disease was present, but in two of these it had preceded the onset of asthma; the third patient was aged 78 and had auricular fibrillation. Some suggestion of cardiac impairment was found in four patients, but there was insufficient evidence to establish the presence of myocardial disease. The authors suggest that the increased intrathoracic pressure during an asthmatic paroxysm may impede the return to the heart of the venous blood and thereby decrease the actual work of the heart.

Surgery.

419. Appendicitis and Tonsillitis.

A. LIACRE (*Bull. Soc. de Thér.*, February 9th, 1927, p. 43) states that the analogy between appendicitis and tonsillitis was noted long ago by Le Gendre, Brun, and Goluboff. Delacour drew attention to the frequency of appendicitis in the subjects of adenoids. In both instances the affected organs showed the same histological appearances and the same susceptibility to pathogenic agents, especially in predisposed individuals. Liacre in the course of a few years has had fourteen cases in adolescents or young adults who since childhood had been subject to attacks of tonsillitis and had all been operated upon for appendicitis. On the other hand, among 200 patients at a spa in whom there was no history at all suggestive of appendicitis, there was also the absence of a history of recurrent sore throat. In a third series of patients at the same spa fifty individuals had suffered from recurrent tonsillitis and appendicitis with or without operation, and three of them while under treatment at the spa developed attacks of acute appendicitis.

420. Congenital Deformities of the Intestine.

R. APPELMANS (*Rev. de Chir.*, No. 10, 1926, p. 729) describes the different varieties of congenital malformation of the intestine. Among the lesions of the small intestine commonly seen are those where there is a valvular formation of the mucous membrane, true stenosis, and complete absence of a segment of the gut. The valvular deformity is formed by a reduplication of the mucous membrane in the form of a diaphragm, obliterating to a greater or lesser degree the lumen of the bowel. True stenosis is the more common type of deformity, the intestine usually being dilated above and atrophied below the constriction. In other cases there may be complete absence of a segment of the ileum, the intestine being divided into two culs-de-sac, the upper being dilated, the lower atrophied. The interval between the two segments is occupied by a thickening of the mesenteric border, or in some cases by nothing at all. The symptoms of stenosis are absence of meconium and vomiting and distension; the only treatment is to establish the continuity of the gut by operation. Among the deformities of the large

intestine megacolon or Hirschsprung's disease is perhaps the best known. In this there is a dilatation and hypertrophy usually affecting the sigmoid. The cause of this condition is unknown, the symptoms being obstinate constipation and abdominal distension; the only treatment is colectomy. Inversion of the gut is rarely seen where the small intestine lies on the right side of the abdomen and the large bowel on the left. It is due to an error of development, and is treated by rotating the gut and fixing the ascending colon and hepatic flexure in its correct position.

421. Cornu Cutaneum Penis.

M. KISMAN (*Nederl. Tijdschr. v. Geneesk.*, February 26th, 1927, p. 1060), who records an illustrative case, states that Friedrich in 1891 collected twenty-one cases of this condition; it occurs more often in old men and is rare in the young. The horn is usually situated on the corona glandis and may attain a considerable size; Hebra has described a case in which it was 4 inches long. Microscopically the horn consists of epidermal cells which in the uppermost layers have no nuclei. At the base the horn cells pass into the normal cells of the epidermis and send offshoots of epidermal cells into the deeper layers. Eleven cases of its development in association with phimosis have been recorded. Other etiological factors are mechanical causes, friction, dirt, and so on. Kisman's case was a Javanese native, aged 33, who had been circumcised under local anaesthesia for phimosis. When seen six months after the operation he presented a horn about 2 inches long in the mid-line proximal to the corona glandis. The patient stated that it had first appeared four months previously as a wart-like thickening. The horn was excised, and there had been no recurrence when the patient was seen six months later.

422. Treatment of Cancer of the Bladder.

F. DE QUERVAIN (*Rev. Méd. de la Suisse Romande*, March 16th, 1927, p. 259) recommends the application of cold for the treatment of vesical cancer, in preference to radium, *x* rays, and operative measures. Therapeutic freezing has been used for some twenty years in the treatment of angiomata and carcinomata of the skin. The elective action of cold against certain neoplastic cells has been studied by Jensen, Ehrlich, Bashford, and others, and the present author holds that by its use it is possible to save the ureters while destroying the cancer. He first employed this method ten years ago, successfully treating a case of multiple papillomata of the bladder. He now reports the successful treatment by carbon dioxide snow of a case in which the bladder contained two cancerous growths, and there was a metastasis in the abdominal wall. Two years subsequently the patient was alive and apparently cured, the vesical functions being normal and there being no signs of recurrence. The snow, in a chamois leather bag, is placed in a compress of four layers of absorbent gauze, the whole forming a spherical ball about the size of a mandarin orange. This is applied to all sides of the tumour with sufficient pressure to cause the cold to penetrate the perivesical tissues and to prevent the intervention of the gas that is formed. The application is continued for at least five minutes, and the bladder is left open to permit further treatment if advisable. De Quervain adds that the healthy vesical mucosa and the ureters resist freezing; though this method may not ensure cure, it causes an appreciable amelioration of the condition with disappearance of the haematuria, and prolongs life for more than a year.

423. Cancer and Life Insurance.

P. MÖLLER (*Ugeskrift for Laeger*, February 17th, 1927, p. 129) states that, according to official returns, there were 4,673 deaths from cancer in Denmark in 1922, this disease being responsible for 11.8 per cent. of all the deaths in that year. Among insured persons in Denmark, two series of investigations (one covering the period 1871–1905, the other 1872–1911) together showed that 12.5 per cent. of the deaths were due to cancer. What was still more striking was the observation that cancer came third in frequency as a cause of death within three years of the issue of an insurance policy. It may be presumed that some of these persons had already developed cancer at the time of the insurance, and the author refers in detail to a case of cancer of the rectum which was overlooked at the time of the medical examination. Until ten years ago it was the custom of the Danish insurance companies to refuse all lives complicated by new growths, even if they had been removed or were supposed to be benign; lipomata were an exception to this rule. In 1916 a group of large Danish life insurance companies formed a special committee to which all these societies could refer those applicants for life insurance who could not be accepted on the usual terms. In the period which has subsequently elapsed this committee has had 41 cases of new growths to deal with, but only in 12 did the parties concerned come to terms. For want of experience with regard to the expectation of life in each class of new growth these cases had to be lumped together in one class, and in most cases the companies insisted on an interval of five years between the issue of the premium and the insured person's right by death to the sum insured. In only one of the 12 cases did death occur within this interval; in 3 other cases the insured person discontinued the payment of the premiums. The nature of the new growths could not always be determined with certainty; some were most probably benign (fibroma of the breast and chondroma of the scapula), while in two-thirds of the cases the new growths were considered to be malignant. The severity of the terms offered was shown by the fact that 29 of the 41 persons refused them.

Therapeutics.

424. Parathyroid Therapy.

J. B. COLLIP (*Journ. Amer. Med. Assoc.*, February 19th, 1927, p. 565) thinks that the active principle of parathyroid extract is probably a complex protein derivative. The parathyroid hormone relieves or prevents tetany when injected into animals from which these glands have been removed, and in dogs a definite mobilization of calcium in the blood stream follows its injection, whether the glands are present or not. With excessive administration the serum calcium content may rise from about 10 mg., the normal average, to 20 mg. per 100 c.cm. Such overdosage, of which vomiting is an early symptom, causes great increase in the inorganic phosphorus, urea, and non-protein nitrogen in the blood, the greater viscosity of which is associated with decrease in the plasma volume and chlorides, and with a marked acidosis and almost complete anuria in the stage before death ensues. The function of the hormone in the normal animal appears thus to be calcium mobilization, and, after death, the tissues are found to contain greatly increased amounts of calcium salts.

425. W. S. MCCANN (ibid., p. 566) discusses the unit of biologically standardized parathyroid preparations in various conditions, and concludes that at present the only definite indications for their administration are tetania parathyreopriva, infantile tetany, and those pathological conditions in which there is a low blood serum calcium content. They may possibly be found later to be of value in the elimination of lead from the body in cases of poisoning; in rickets, apart from the control of tetany; and in the convulsions of pertussis. Their influence on the regulation of blood pressure and renal function are also being studied. McCann adds that their use must be controlled by frequent and accurate determination of the calcium content. Values higher than 12 mg. per 100 c.cm. are undesirable, and when over 15 mg. may be dangerous. Local irritation is often pronounced after injection, and it is doubtful whether long-continued use is possible without the administration of calcium.

426. Vaccine Therapy in Staphylococcal Infections of Children.

W. POCKELS (*Monatssch. f. Kinderheilk.*, March, 1927, p. 229) has been investigating the action of vaccines in various diseases of children. He states that cases of *B. coli* infection, urinary as well as intestinal, are uninfluenced both by injections of autogenous vaccines and by their oral administration in tablet form. In staphylococcal infections, on the other hand, he finds them of definite value. In a series of eight children accidentally infected by staphylococci four were given three tablets of solid staphylococcal vaccine daily; they healed more quickly and had a less severe reaction than the other four, who were not given a vaccine of any kind. This conclusion has been confirmed experimentally in the case of staphylococcal infection of rats.

427. Sodium Chaulmoograte in Leprosy.

E. BALBI (*Giornale Ital. di Dermat. e Sifilol.*, Fasc. ii, 1926, p. 623) treated five cases of advanced leprosy with a 3 per cent. solution of sodium chaulmoograte. He aimed at saturating the system with the salt by slowly increasing the dose up to the limit of toleration, small quantities up to 40 cg. being given intravenously every second day, followed by intervals of twenty-five days after each series of twelve injections, so as to minimize the toxic effects. Good results were obtained in one mixed and one tubercular leprosy case in which treatment was continued for eight and six months respectively, the total amounts of salts given being 17 grams and 12 grams. In a third case, of mixed leprosy, dennite improvement followed the administration of a total dose of 7 grams of the salt in three months. The two remaining patients showed less improvement, the treatment having been shorter and less intensive. With the exception of the third case the patients were in the tertiary stage of the disease; there was profound trophic disturbance, both local and general, and the natural defensive powers were obviously

inadequate. Complete disappearance of Hansen's bacilli from the nasal secretions followed two and a half months' treatment in the third case, but the bacilli reappeared five months after its suspension. No change occurred in the Wassermann reaction in any case, and the complement-deviation test was positive in all five cases, both before and after treatment. Injection of sodium chaulmoograte caused first a leucopenia, which was followed by leucocytosis up to 14,000 per c.mm. Febrile reactions were usually provoked by the injection, the fever lasting from two to twenty-four hours and abating generally during sleep; the reactions were probably attributable to the toxins caused by bacteriolysis (Rogers). In some cases it was found better to dilute the chaulmoograte solution to one-half or one third strength. Balbi concludes that the intensive injection of this salt, if continued sufficiently long, is one of the best remedies for leprosy, and that it is particularly beneficial, intense, and rapid in chronic cases. It is necessary, however, to estimate carefully the tolerance of each patient so as to diminish as far as possible the general toxic reaction to this preparation.

423. Novarsenobenzol in Perineal Pruritus.

H. KHOUBESSERIAN (*Thèse de Paris*, 1926, No. 288) records five illustrative cases, three of which were in women aged 40, 49, and 38, and two in men aged 54 and 51, suffering from vulvar or anal pruritus, of which the duration had ranged from a few months to several years. On inquiry a more or less definite history of acquired or inherited syphilis was obtained and a rapid cure was effected by treatment with novarsenobenzol. The author recommends that in all cases of perineal pruritus where the ordinary methods of treatment have failed to produce relief an antisyphilitic course should be tried before handing over the patient to the surgeon for superficial neurotomy or resections of the mucous membrane.

Neurology and Psychology.

429. Ketonaemic Nervous Disturbances in Children.

ACCORDING to H. C. CAMERON (*Arch. Dis. in Childhood*, February, 1927, p. 55), acetone bodies appear in the breath and urine of children during infection marked by considerable pyrexia, during fasting, in severe vomiting after anaesthesia, when given a diet rich in fat and poor in carbohydrate, and when excited or overfatigued. Coincidently with the rise in the amount of ketone bodies in the blood there is a corresponding fall in the alkaline reserves and a considerable, though sometimes short-lived, reduction of the blood sugar. In children prone to cyclical vomiting this response is of maximum intensity. Such children come of an intellectual and nervously sensitive stock, prone to exhaust themselves by the energy they expend in the business of life. With an unstable nervous system a relatively unstable metabolism may perhaps be taken for granted, and one will react on the other. These children are subject to sudden attacks which may or may not culminate in excessive vomiting; amyotonia with transient muscular pains, vasomotor pallor, cardiovascular weakness, abdominal pain or discomfort, and irregular pyrexia are the most common symptoms. Constipation is usual, but headache and giddiness are only occasional complaints. When the vomiting is worst acetone is generally detectable in the breath and in the urine, but its presence in great amounts often follows and does not precede the vomiting. Treatment should be directed to management, diet, and the removal of infection. When busy, happy, and occupied these children thrive and are often free from attacks. The diet should be antiketogenic, with a relatively high intake of sugar. An alkaline aperient may be administered daily. Infection should be dealt with whenever present; it is often a cause of the metabolic disturbance, but may be the result.

430. Diagnosis of Pyramidal Tract Irritation.

IN view of the frequent failure to elicit the signs of Babinski, Oppenheim, and Schaefer in disease of the pyramidal tract, J. A. SICARD (*Presse Méd.*, February 26th, 1927, p. 257) suggests the use of osseous percussion instead of tickling the sole of the foot, brusque flexion of the toes, and pinching of the dorsum of the foot. This procedure consists in laying the lower part of the leg in the open palm and shaking the foot in a lateral, but not antero-posterior, direction. The shaking should be rapid and last about half a minute, and its cessation should also be sudden. The foot may be either raised or allowed to rest on the bed; in the latter case a double excitation is caused both by the shaking and also by the friction of the sole on the bed. A positive response is indicated by an extension of the great toe only, by extension of all the toes, by extension of the great toe and flexion of the other four, by dorsal flexion of the foot alone, by flexion of the foot on the leg and of the leg on the thigh, or by a combination of any two or all of these. A more pronounced response is often elicited by lightly flexing the lower limb in its whole extent, leg on thigh, thigh on pelvis. Sicard considers this response to be a defensive spasm reflex of pyramidal origin, and it is always present in spasmodic paraplegias with medullary compression, or paraplegias of central origin. It is never elicited in normal states or in paraplegias of parapyramidal origin, conditions in which the other signs are often positive and lead to erroneous diagnosis.

431. Vertigo in Epidemic Encephalitis.

L. LEQUINT (*Thèse de Paris*, 1926, No. 211), who records eight cases, including two not hitherto published, describes a special form of epidemic encephalitis characterized by vertigo. The pure form is very rare, and as a rule there is a coexistence of signs of vestibular involvement with ocular and other symptoms. The differential diagnosis of this form of encephalitis from other diseases of the internal ear and nervous system, especially disseminated sclerosis and syphilis of the nervous system, may be very difficult. The prognosis even in the mildest cases should be guarded, owing to the frequent persistence of ocular symptoms and signs of vestibular involvement and the possible occurrence of later complications such as Parkinsonism, as in other forms of epidemic encephalitis.

432. Dermatitis as a Psychological Manifestation.

W. J. O'DONOVAN (*Brit. Journ. Derm. and Syph.*, February, 1927, p. 49) records several cases illustrating a psychological factor in dermatitis, and recommends the routine examination of a patient suffering from dermatitis to ascertain whether there is an emotional history, evidence of mental injury, or whether any such causes are operating as are known to prolong invalidity after ordinary surgical accidents. Examples are given of eruptions which were resistant to ordinary treatment but were cured by sedatives, being due to mental shock. In some cases suggestion was found to be the sole factor in the production of an extensive and long-standing superficial dermatitis, which in others followed some minor injury. In two cases of varicose ulcers neurasthenia was responsible for their chronicity, and O'Donovan considers that patients of this type derive a morbid satisfaction and an outlet for their repressed feelings in a constant consideration of their ulcers, which receive little surgical rest, good results following the application of an occlusive dressing combined with sedative treatment. He adds that the effect of the Workmen's Compensation Acts in delaying recovery is evident in dermatological work, and notes of cases of dermatological malingering and of traumatic cutaneous neurasthenia are quoted in support of this view.

Obstetrics and Gynaecology.

433. Treatment of Puerperal Sepsis by Local Application of Vaccines.

P. TRON (*Zentralbl. f. Gynäk.*, January 29th, 1927, p. 298) remarks that local application of vaccines, according to Besredka's method, is subjected in puerperal sepsis to a severe test, for the circumstances are exceptionally favourable to a generalization of uterine infection in that the casting off of the placenta opens widely the maternal blood vessels and the uterine and abdominal cavities communicate freely by means of the Fallopian tubes. Nevertheless, he is favourably impressed, on the whole, by the result of the application by Besredka's method of vaccines to the vagina, perineal wound, or uterus, on gauze tampons or by intra-uterine douching. The vaccine used was a polyvalent filtrate, prepared at the Pasteur Institute, from staphylococci or streptococci incubated from fourteen to sixteen days in broth. The earliest application was of a mixed staphylococcal and streptococcal filtrate; from the second day a staphylococcal or streptococcal filtrate alone was used, according to the bacteriological findings from examination of the discharge. It was found to be important that the filtrate should be used in the earliest possible stages of the infection; after one or two applications the local conditions showed macroscopically a well marked increase in cleanliness and microscopically distinct phagocytosis.

434. Pelvic Pain in Women.

H. H. SCHMID (*Med. Klinik*, February 25th, 1927, p. 271) describes and classifies cases of pelvic pain in women. He first excludes extrapelvic causes, such as sciatica, chronic arthritis of the hip or sacral joints, disease of the vertebrae, flat-foot, coxa vara, appendicitis, stone in the kidney or ureter, and then extragenital causes, such as stone in the bladder. Enteroptosis was responsible for 70 per cent. of the remaining cases of persistent dull aching pain in the lower part of the abdomen or back. They are diagnosed by having the patient in the erect position, and supporting the lower part of the abdomen with both hands; often the pain

disappears, to return when the support is relaxed. These patients are treated by a fairly tight belt or support over the lower part of the abdomen. In dealing with the purely genital cases, Schmid gives a warning against the assumption that retroversion of the uterus always causes pain: pain may persist even after perfect correction of the displacement. In these genital cases the pain is usually felt at a lower level than in the former classes. On examination traces of old pelvic peritonitis are usually found, or a fixed retroversion, or adhesions between the fundus uteri and pelvic colon. Schmid describes a group of cases in which the utero-sacral ligaments are shortened, often thickened, and tender. In these cases there may be no history or signs of parametritis; they are often associated with chronic constipation and straining, or with irregularities of sexual life, such as masturbation or coitus interruptus; spasm of the unstriped muscle of the ligaments has occasionally been observed. Pain may only be felt at certain times—as, for example, during defaecation or sexual intercourse—and can be aroused for diagnostic purposes by pressing forward towards the symphysis pubis with the finger in the posterior vaginal fornix or in the rectum. The treatment of all these cases is—(1) local applications, hot sitz baths, long hot vaginal douches, and vaginal diathermy; (2) mechanical treatment—massage, stretching of the ligaments under anaesthesia; (3) antispasmodic remedies, such as atropine, papaverin, and camphor; and (4) operative procedures. Injections are made into the ligament or its neighbourhood. Schmid injects from 20 to 40 c.cm. of a 1/2 per cent. to 1 per cent. solution of novocain through the posterior vaginal fornix.

435. Cirsoid Aneurysm of the Uterus.

E. LOUBAT (*La Gynécol.*, January, 1927, p. 15) records the case of a woman, aged 62, who had suffered at a few months' intervals from alarming attacks of uterine haemorrhage, of which the first occurred ten months after the menopause; slight blood-stained discharge was reported during the intervals. The cervix was of normal size and configuration and the corpus uteri bulky; in both lateral fornices vigorous pulsations of an artery as thick as a lead pencil could be felt, accompanied by a slight thrill. Diagnosis was thought to lie between carcinoma of the corpus uteri and an angiomatous tumour. At the operation the enlarged body of the uterus showed a small rounded swelling on the upper portion of the anterior surface; the whole uterus pulsated forcibly and a systolic thrill could be felt. The subperitoneal juxta-uterine veins were as large as the jugular veins. Histological examination showed the myometrium to be extensively replaced by cirsoid tissue with arterio-venous communication.

436. Extrauterine Pregnancy.

B. C. HARDIMAN (*Canadian Med. Assoc. Journ.*, March, 1927, p. 297) reports five cases of ectopic gestation and outlines the history of the treatment of this condition, since the time when almost certain death was the outcome to the present day when the mortality has been reduced to below 5 per cent. An important factor in the occurrence of ectopic gestation is abnormality of the Fallopian tubes, such as inflammation, parametric exudation, and malformations, including diverticula and accessory tubal canals, usually associated with protracted sterility. This possibility should be remembered in the case of a married woman complaining of irregular haemorrhages and colicky pains; the necessary vaginal examination should be made very gently and care be taken to avoid mistaking a retroverted uterus for ectopic pregnancy. A tender elastic mass behind or at one side of the uterus, associated with a history of irregular haemorrhages, spasmodic or tearing pain, faintness and thirst, calls for immediate laparotomy.

Pathology.

437. Atypical Tubercle Bacilli.

PIRONET (*Arch. Méd. Belges*, February, 1927, p. 53) gives a short account of the nature of the polymorphism of the tubercle bacillus. Vaudremer showed that tubercle bacilli could grow on media of low nutritive value. When sub-cultured from colonies on agar without glycerin the bacilli are found to have lost completely their resistance to acid; they stain by Gram's method, and certain strains no longer infect guinea-pigs. Grown on potato broth without glycerin, the bacilli on the surface are longer than ordinary tubercle bacilli and are feebly acid-resistant, but below the surface polymorphic forms appear which stain well by Gram's method and are not acid-resistant. The young bacilli grow large and develop branches and buds which become detached. On filtration through a Chamberland L_3 filter, culture of the filtrate yields similar branching, non-acid-fast filaments. When these are inoculated subcutaneously in guinea-pigs they produce a local induration which disappears in two or three weeks without causing generalized tuberculosis. In guinea-pigs intravenous inoculation produces a chronic generalized polyadenitis and occasionally periarthritis. In some cases after three or four months a gland breaks down. On making a culture from the pus on Petroff's medium, acid-fast granules are found; after a series of sub-cultures on the same medium the bacilli revert to the normal acid-fast form. When acid-fast granules are injected subcutaneously they produce a scar, which disappears in five or six weeks and is not followed by tuberculosis. When injected intravenously, if they do not kill the animal in eight days they confer local but not general immunity, and no inoculation sore follows the subsequent inoculation of virulent tubercle bacilli. When a normal culture of tubercle bacilli on glycerinated potato is emulsified in physiological saline solution and filtered through a Chamberland L_3 candle the filtrate yields non-acid-fast forms of mycelial type. After filtration of tuberculous sputum or pus, guinea-pigs inoculated with this filtrate died with lesions containing typical tubercle bacilli. But in tuberculosis thus produced there was no inoculation sore and the corresponding lymph node was not enlarged. At the autopsy the viscera appeared healthy and the tracheo-bronchial and cervical glands were normal or slightly enlarged; there were no histological lesions, but the fluid expressed from the glands contained typical tubercle bacilli. Such filterable forms can traverse the placenta, for inoculation of the mother is followed by the appearance of typical tubercle bacilli in the foetus.

438. A Photographic Method of Counting Blood Cells.

IN order to eliminate the error in counting incurred by the use of the ordinary haemocytometer method A. H. SANFORD (*Journ. Lab. and Clin. Med.*, February, 1927, p. 456) has devised a simple photographic method of counting blood cells. Instead of making the counts directly under the microscope, a photograph is taken of 100 squares of the haemocytometer field, and the cells are counted on the positive print. Using a Spencer microprojector as the source of illumination, an 8 mm. objective, a 6× eyepiece, and an ordinary view camera, he obtains satisfactory results on process films with a two seconds' exposure. The magnification is about 200. The cells are counted on the prints, and to avoid counting the same cell twice he pricks it with a needle connected to an automatic counting machine. A comparison of counts made in this way with those made by a direct microscopic count of the haemocytometer slide reveals a small discrepancy, the former method giving the higher values. This the author considers to be due to the uneven focusing of the slide under the microscope. In a photograph of the slide all the cells are reproduced, even though they are not all in perfect focus; but when a direct count is made the observer, in endeavouring to focus all the cells clearly, inevitably throws some out of focus, so that these are missed. At present he advocates the photographic method for research use only, considering that the extra trouble involved is compensated by the greater accuracy of the results.

439. Cardiac Action of Calcium Chloride.

E. FROMMEL (*Arch. des Mal. du Coeur, des Vaisseaux et du Sang*, February, 1927, p. 85) comments on the use of calcium chloride as a cardiac tonic, and states that the principal objection is that it must be administered intravenously, which is painful. It may be dangerous in heart disease, since by increasing the coagulability of the blood it enhances the risk of thrombosis and embolism. Calcium chloride has been so efficacious in the treatment of persistent vomiting of pregnancy, in haemoptysis, and in diarrhoea due to tuberculosis that its other uses have been neglected. The author reports that immediately after the injection of a 5 per cent. solution in a frog's heart a powerful ventricular contraction occurred, followed later by a similar auricular contraction. These effects resemble, at least in part, those produced by stimulation of the pneumogastric nerve. It has been suggested that calcium increases vagal tonus, but Frommel's experiments on rabbits showed that similar disturbances of cardiac rhythm occurred in rabbits with paralysed or divided pneumogastric nerves and in normal animals. He is uncertain whether calcium acts directly upon the myocardium or on the intracardiac nerve ganglia. The chloride slows, strengthens, and prolongs systole, while diastole is less complete. In both the frog and rabbit death results from tetanic ventricular contraction, the ventricle is hard, pale, and so strongly contracted that the cavity is practically obliterated. He concludes that calcium chloride modifies cardiac excitability and conductibility, both in healthy animals and in those in which the pneumogastric nerves have been damaged. These latter animals, however, require larger doses and appear to be less sensitive to the drug.

EPITOME OF CURRENT MEDICAL LITERATURE.

Medicine.

440. Diabetes in Children and Infections.

R. LECOCQ (*Thèse de Paris*, 1926, No. 266), who reports seventeen illustrative cases, states that although almost all infectious diseases have been reported as giving rise to diabetes mellitus this etiology has very rarely been proved. Mumps and syphilis have furnished undoubted examples of diabetes in children following an infection, but such cases are very rare. While infections are not usually the true cause of diabetes, they often appear to provoke symptoms in those who are predisposed, as in cases where diabetes has manifested itself after an attack of appendicitis. The influence of infections on the course of diabetes in children is very variable. Increase in glycosuria appears to have been more frequently noted than its diminution. The latter when it occurs is probably due in large degree to the change in the diet. Increase in glycosuria, on the other hand, appears to be the sign of an aggravation of the disease due to the infection, whether through the pancreas, nervous system, or some other channel. The general course of diabetes in children appears to be aggravated in most cases by the supervention of an infection such as scarlet fever or typhoid fever, especially when the strictness of the regimen has been relaxed. On the other hand, if the patient is carefully treated, the intercurrent disease does not aggravate the course of diabetes, apart from tuberculosis and infections, such as mumps, which are liable to affect the pancreas. Insulin is a valuable addition to the treatment of diabetes in children, and enables them to offer a better resistance to intercurrent infections.

441. Glandular Fever.

H. A. SALVESEN and R. MAGNUSSON (*Norsk Mag. f. Laegevidensk.*, March, 1927, p. 189) review the literature, including the paper by H. L. Tidy and E. B. Morley (BRITISH MEDICAL JOURNAL, 1921, i, p. 452), and record two cases in men, both aged 23. The attack in each case was characterized by fever, moderate enlargement of the lymphatic glands, especially in the cervical region, sore throat, and a leucocytosis with a lymphocytosis of 75 per cent. Cultures of the throat showed streptococci and staphylococci only. In one case the blood was examined after an injection of sterile milk during convalescence, when a neutrophil leucocytosis was found.

442. Immunization against Diphtheria.

M. P. GLUSMANN, J. W. SOLOWJEWA, and I. N. GLADSTERN (*Zeit. f. Hyg. u. Infektionsk.*, January 27th, 1927, p. 130) have made a number of experiments on guinea-pigs and children with formolized diphtheria toxin (anatoxin). They found that the addition of 0.2 to 0.3 per cent. of formol to the toxin was sufficient to lower its toxicity in two to six days at 37.5° C. to about one-hundredth of its initial value. The resulting anatoxin was not completely innocuous. When diluted 1 in 20 and injected into guinea-pigs in a dose of 5 c.cm. it gave rise to a marked infiltration and sometimes death—though not in less than five days. Three injections of the anatoxin rendered about 90 per cent. of children immune in a little over a month. Comparisons with immunization by the toxin-antitoxin method showed that it had no superiority over this method, and they therefore see no reason for preferring it in practice.

443. PROGULSKI and F. REDLICH (*Wien. klin. Woch.*, March 3rd, 1927, p. 284) have immunized Schick-positive children with anatoxin following the directions of Ramon, and using doses of 0.5 c.cm. subcutaneously at the first injection, 1 c.cm. after fourteen days, and 1 c.cm. after three weeks. Four to eight weeks later the Schick tests were repeated. Out of 121 children treated 102 gave negative reactions, and of the remaining 19 the reactions were distinctly weak. In 9 cases, although the blood, examined according to the Roemer method, was found to contain no antitoxin, or only a negligible amount, there was evidence of a definite protection against [illegible] sing of the antitoxin titre. In 13 cases t[illegible] " of Kraus was used, subcutaneous injections of 0.1 c.cm. in 2 c.cm. saline being given three times every third day. After forty days the Schick reaction was negative in 11 children and only slightly positive in 2; the protection is said to be complete. The authors add that the Kraus diphtheritoxoid has an advantage over the anatoxin of Ramon in that the immunizing process requires only eight days, which is an important consideration, especially during a diphtheria epidemic. Children stand the injections of anatoxin and diphtheritoxoid equally well. The frequent occurrence of local reactions is unimportant as these pass off in from twenty-four to forty-eight hours. General symptoms such as fever and headache were only rarely observed.

444. The Dick Reaction at Different Ages.

S. HELLER (*Med. Klinik*, March 4th, 1927, p. 320) has studied the Dick reactions in 1,112 patients of various ages; the result of the test was positive in 47.6 per cent. He considers the variations at different age periods important. In twenty newly born babies the result was negative in all, although two of the mothers showed positive reactions. Schultz and Charlton found that the subcutaneous injection of 0.5 to 1 c.cm. serum from a convalescent caused fading of the rash at the site; this has been confirmed by many observers, and this property of the convalescent serum is regarded as specific. Heller has observed the same process after injection of serum from an infant, showing that its immunity is specific and confirming the observations of Hainiss. The greatest sensitiveness is found between the ages of 2 and 5 years; after prophylactic injection 75.5 per cent. of such children were negative. A weak positive reaction becomes negative more readily than a strong positive. The author thinks that younger children are more difficult to immunize, partly because of their higher sensitiveness to the disease and partly owing to the greater difficulty they have in forming antitoxins. He gives three important results from the Dicks's work: estimation of the individual sensitiveness to scarlatina, active immunization, and a form of specific treatment in advance of any yet known. He adds that time will show the prophylactic benefit of these injections; their therapeutic value is already established.

Surgery.

445. Ramisection in Hirschsprung's Disease.

R. B. WADE and N. D. ROYLE (*Med. Journ. of Australia*, January 29th, 1927, p. 137) report and discuss two cases of Hirschsprung's disease (congenital megalocolon). In one extirpation of the colon failed to effect a cure, the dilatation reappearing in the ileum close to the anal sphincter, while in the other benefit followed a specially designed lumbar sympathetic ramisection on the left side, the white ramus to the first lumbar ganglion and the medial branches from the first, second, third, and fourth lumbar ganglia being severed and the trunk cut across below the fourth ganglion. The condition appears to be due to failure of the sphincter to relax owing to overaction of the sympathetic. By the daily use of enemata relief can be obtained, but the trouble tends to recur, while ramisection is considered a simple procedure free from operative risk, and it is held that the authors' second case shows that a hitherto intractable condition can be relieved by cutting part of the sympathetic nerve supply to the large bowel. The method used differed from an ordinary ramisection in that the medially directed fibres passing to the hypogastric and inferior mesenteric plexuses were divided, and not the laterally directed rami communicantes of the second, third, and fourth lumbar nerves. The authors conclude that the results of such treatment in Hirschsprung's disease and similar conditions open up great possibilities, since persistent constipation and visceroptosis can be relieved by the safe procedure of ramisection.

446. Perforation in Gastric and Duodenal Ulcer.

SERRADA (*La med. Ibera*, February 26th, 1927, p. 233) gives the following statistics for perforation in peptic ulcer: 28 per cent. for duodenal ulcer (Mayo brothers); 12.5 per cent. for duodenal ulcer, and 9.5 per cent. for gastric ulcer (Buel); and 6 per cent. for gastric and duodenal ulcers in his own experience. Recovery followed in 50 per cent. of the patients on whom Serrada operated for perforation. The following recovery rates were obtained by various surgeons who operated within six hours of the perforation; 61 per cent. (Hartmann), 92 per cent. (Duval); after a lapse of twelve hours the mortality is 33 per cent., and after twenty-four hours from 80 to 100 per cent. After thirty-six hours an operation is considered useless, since the patient is doomed. The perforation may be preceded by sharp pain, slight fever, nausea and vomiting, or may occur suddenly without any

prodromes, being manifested by agonizing pain, contraction of the recti abdominis, loss of hepatic dulness, shock, and early phrenic dyspnœa. Perforation of peptic ulcer must be distinguished from hepatic colic, which is often preceded by a history of gastric disturbance and accompanied by pain sufficiently severe to produce symptoms of shock, perforation of the appendix, hæmorrhagic pancreatitis, and perforation of the gall bladder.

447. The Undescended Testis.

O. H. WANGENSTEEN (*Archives of Surgery*, March, 1927, p. 663) reviews the literature and describes his own experimental work, which included the transplantation of testes into the abdominal and inguinal region, determination of testicular reaction to injury, transference of the testis to the peritoneal cavity or inguinal region with later replacement into the scrotum, and ligature of the vas deferens and of the blood vessels. Several undescended human testes, removed during hernia operations, and many normal ones were also examined. He concludes that undescended testes in the human adult are nearly always aspermatic. They form mature germinal cells, but their aberrant position does not permit of the continuance of spermatogenesis. The testes before puberty and of the newborn differ but slightly in weight, and the histology is practically the same. The undescended testis before puberty is histologically similar to a scrotal one of the same age. If placed in the scrotum without vessel damage before puberty, the undescended testis will develop normally. Tying all the vessels to the testis with the exception of the artery and vein accompanying the vas deferens is followed by destruction of the testis. Scrotal fixation does not minimize the possibility of an undescended testicle becoming malignant. He adds that castration in the absence of complications is too radical a proceeding in the management of undescended testes.

448. Left Subphrenic Abscess.

M. NOGUERAS (*Arch. de med. cir. y esp.*, February 26th, 1927, p. 292) states that a subphrenic abscess on the left side may be due to any of the following causes: a suppurative process in the upper half of the spleen, infected blood cysts or hydatid cysts of the same organ, perforation of the greater curvature of the stomach on its posterior aspect, perforation of the duodenum in the neighbourhood of and above Treitz's ligament, perforation of the posterior aspect of the splenic flexure of the colon, localized peritonitis of this gastro-splenic region, suppurative process of the ribs or vertebral column, suppurative pleurisy and pericarditis which pass through the diaphragm, and open or closed wounds giving rise to extravasations of blood which subsequently become infected. The contents of the abscess may be blood-stained pus, remains of hydatids, carious bone, caseous masses, and almost invariably fetid gas which occupies the greater part of the cavity. In addition to more or less general disturbance the symptoms consist of a swelling in the left hypochondrium with elevation of the ribs, sharply defined tenderness on pressure, occasionally œdema and redness of the skin, and an upper zone of tympanism and a lower zone of dulness when the patient is sitting or standing. Although the prognosis of subphrenic abscess on the left side is not so grave as on the right Mayo reports a mortality of 56 per cent., Elsberg of 40 per cent., and Sonenburg of 42 per cent. Treatment consists in early operation under a local anæsthetic, which will reduce the mortality to 15 to 20 per cent.

Therapeutics.

449. Tryparsamide in General Paralysis.

S. B. HADDEN and G. WILSON (*Journ. Amer. Med. Assoc.*, February 12th, 1927, p. 473) state that tryparsamide has been shown, by its use in neurosyphilis and trypanosomiasis, to be more penetrable than the ordinary arsenicals, and therefore more potent in acting on the central nervous system. Its only unfavourable property is its tendency to produce amblyopia in a small percentage of cases. The authors have obtained excellent results from its use in the treatment of fifty-two cases of general paralysis, the benefit being greater than with other arsenicals, mercury, or bismuth. The patients gained in weight and general health, and the tremor of the face, tongue, and lips, and consequently the speech defect, considerably improved. Those who have received this treatment do not show such a tendency to develop trophic sores as do the untreated. Only seven patients showed any bad effects, two developing jaundice, one dermatitis, two Herxheimer's reaction, and only two serious visual defects. The dose of tryparsamide is 3 grams in 10 c.cm. of distilled water; one dose a week is given, and after ten doses a six weeks' rest follows. Before treatment a careful ophthalmic examination should be made. If any visual symptoms appear treatment should be stopped, and resumed only when these disappear. The clinical benefit obtained far surpassed the serological improvement; other authors have reported better serological results when this drug is combined with mercury, bismuth, or some other arsenical, a procedure recommended by the present authors. They believe that tryparsamide produces beneficial results in 40 per cent. of cases, and that it is by far the best drug to use in the treatment of general paralysis.

450. Serum Treatment of Weil's Disease.

W. A. TIMMERMAN (*Nederl. Tijdschr. v. Geneesk.*, March 26th, 1927, p. 1572) states that though only fifteen cases of spirochætosis icterohæmorrhagica have been recorded in Holland during the last two years, more have undoubtedly occurred. Schüffner has been able to collect twenty-five cases, with a death rate of 32 per cent., while the mortality of those cases following a fall into water was as high as 45 per cent. In view of the increasing number of cases of the disease in Holland a therapeutic serum has been prepared at the Dutch Serological Institute at Utrecht by injecting rabbits with the *Leptospira icterohæmorrhagiæ*. Rabbits are used instead of horses, which require a long time and great quantities of leptospiræ to become immune. It is recommended that the serum should be given as soon as possible after the diagnosis has been made, the intramuscular route being used except in very severe cases, in which the intravenous method is employed. The quantity of serum to be given will depend on the stage of the disease and the severity of the attack; an average initial dose of 30 c.cm. intramuscularly is certainly not excessive. The further course of the disease will determine whether the dose need be repeated or not. It is added that, though it is impossible to prevent all deaths from Weil's disease by using this serum, the treatment will certainly reduce the mortality very considerably; omission to give it at the right time must be regarded as an error of judgement.

451. Alcohol in Acute Infectious Diseases.

J. D. ROLLESTON (*Clin. Journ.*, March 9th, 1927, p. 109) remarks that recent investigations have shown that there are no grounds for regarding alcohol as a cardiac stimulant. The most that can be said for it is that it acts as a narcotic and that in adults accustomed to its consumption it produces a sense of euphoria. In the case of children, who form the great majority of patients suffering from acute infectious diseases, there does not appear to be any justification for its use. Rolleston states that it is more than twenty years since he abandoned the therapeutic use of alcohol; during the last ten months, since his appointment as medical superintendent of a fever hospital, the amount of alcohol ordered on the diet sheets has fallen from an average of about 30 ounces daily to *nil*, without any evil effects; the mortality from diphtheria, in which disease most of the alcohol was used, was lower in 1926 (4.53 per cent.) than in the previous year (5.19 per cent.). During the last quarter of 1926 the total amount of brandy ordered, though not entirely consumed, was only 2½ ounces, as compared with 1,112 ounces during the corresponding period of the previous year, the average number of patients under treatment in these two periods being approximately the same (about 400 on any given day).

452. Ephedrine Sulphate.

R. D. RUDOLF and J. D. GRAHAM (*Amer. Journ. Med. Sci.*, March, 1927, p. 399) have examined the therapeutic action on human beings and animals of ephedrine, the active principle of the Chinese herb ma huang. They found that ephedrine raised the blood pressure and slowed and strengthened the heart beat in man, though not in animals, in which the pulse was quickened, possibly owing to the vagal tone having been removed by the anæsthesia. They recommend it, therefore, in the treatment of conditions where the blood pressure is too low, and especially for preventing or combating the fall in blood pressure caused by spinal anæsthesia. Some evidence was obtained that the drug tended to relieve asthma and to raise the blood sugar content. When applied locally to mucous membranes, a blanching and shrinking effect was produced without any adverse sequels. The difference in the effects produced by the drug when given by the mouth, subcutaneously, or intravenously was found to be only one of degree. The authors administered the drug usually in single doses of 50 to 100 mg. of the sulphate in solution, and found that its efficacy was not destroyed by prolonged boiling or by exposure to light for a considerable time. They conclude that ephedrine has very much the same action as has adrenaline, but its effects are much more lasting, and are, moreover, produced when the drug is given by the mouth.

Laryngology and Otology.

453. Latent Influenzal Otitis in Children.

P. GAUTIER (*Rev. Méd. de la Suisse Romande*, February 28th, 1927, p. 104) discusses the frequency of otitis in children, and the difficulty in its diagnosis. He states that the recent influenzal epidemic showed that latent otitis was of common occurrence; it is easy to overlook this complication. Early and energetic treatment is important. Latent otitis is often found in infants and in older children, either alone or as a complication of some other disease, though influenza has not been described previously as one of the most frequent causes. Gautier describes four cases of latent otitis in children whose ages ranged from 11 months to 8 years. In each case hearing appeared to be perfect, and there were no symptoms of otitis, but examination of the membrana tympani showed that there was otitis media, and paracentesis revealed the presence of pus, its evacuation being followed by speedy recovery. The author concludes that every case of prolonged fever, whether oscillating or remaining at a high level, without pulmonary or abdominal symptoms, should lead to an immediate examination of the ears, even when no mastoid tenderness, otorrhœa, or deafness is present. Paracentesis confirms the diagnosis and gives almost immediate relief. The temperature falls quickly and, in general, the otitis is cured most rapidly when it has been recognized at the earliest moment. Latent otitis, when not detected, may persist for weeks and produce most serious symptoms. The majority of these patients suffered also from adenoids, and Gautier considers it most important that these should be removed in order to prevent a recurrence of otitis media, with the grave dangers of mastoiditis and meningitis.

454. Surgery of the Frontal Sinus.

C. FERRETTI (*Arch. Ital. di Otol.*, February, 1927, p. 82) describes the course and treatment of seven cases of frontal sinus conditions varying from an acute sinusitis to a chronic mucocele. He concludes that an *x*-ray photograph is essential in these cases so that the size and shape of the sinus may be determined, and that all secondary prolongations may be dealt with. He believes that the ethmoidal labyrinth is always infected with the frontal sinus, and he recommends that this system of cells be opened and curetted at the time of operation. He does not think it necessary to remove the whole of the anterior wall of the sinus and its floor, and he only makes an opening large enough to clean and inspect the inner walls of the sinus and to ensure efficient drainage by the fronto-nasal canal. This is achieved by removing a part of the frontal process of the maxilla with a portion of the anterior extremity of the middle turbinal bone and dilating up the remains of the canal. He insists on the importance of closing the wound at once without any drainage. He claims that this technique will cure any case of sinusitis, that the resulting scar will be almost invisible, and that there will be no depression over the area of operation.

455. Abscess of the Frontal Lobe following Sinus Disease.

G. PORTMANN and N. MOREAU (*Rev. de Laryngol. d'Otol. et de Rhinol.*, January 15th, 1927, p. 1, January 31st, p. 41, and February 15th, p. 81) discuss the occurrence of abscesses of the frontal lobe of the brain following suppuration in the frontal sinuses. The condition occurs about puberty, and its frequency increases from then to a maximum at about the age of 30, whence it decreases, until examples are almost unknown after the age of 55. Approximately two males are affected to one female. Tuberculosis, diabetes, and syphilis appear to be without influence on its occurrence. As in ear conditions, it is the recrudescence of a chronic or a quiescent suppuration that appears to be most commonly followed by an abscess. Minor traumata acting on an infected sinus appear to influence its spread, and incomplete operations which leave behind infected pockets and fronto-ethmoidal cells are likely to be followed by an abscess. Careful search has to be made at the time of operation for subsidiary cells and reduplicated sinuses. The purulent infection may spread directly through the posterior osseous wall of the sinus and finally reach the brain, or it may pass along the walls of an infected vein. The abscess forms in the frontal lobe, is usually pyramidal in shape, and is limited in its backward progress by the anterior extremity of the lateral ventricle. It varies in size from that of a small nut to a hen's egg. It may be single, may have diverticula, or there may be several small abscesses just under the cortex. The contents are yellow or greenish-yellow pus and may include some gas; there is usually a very fetid collection of pus. Localizing symptoms are absent, and in the presence of a frontal sinus suppuration attention is drawn to the brain by signs of intracranial tension. Frontal headache is the most common sign, and vomiting, and slowing of the pulse and of cerebration may follow. There is rarely any papilloedema, and attempts at localization are difficult. In the earlier stages changes of a psychical nature somewhat similar to the grandiose ideas of general paralysis may be noticed, and the conversation may take on a very childish strain. There is often a marked and unnatural loquacity. As the disease progresses there is a weakening of judgement, of memory, and of will, and a confusion of ideas. The olfactory function is interfered with, and this, if unilateral, is of great value in localization. In large abscesses the motor area may be affected, giving rise to epilepsy, or sometimes, in very late cases, to paralysis. There are four stages in the formation of an abscess. In the first there are slight fever, headache, and slight vomiting; this may go on to acute encephalitis, or more usually it subsides and the condition falls into the second stage of remission; the third stage is that of manifestations of intracranial pressure and irritation; the fourth is the terminal stage, in which coma follows the continued increase of pressure, or death is caused by irruption into the lateral ventricle.

453. Anaesthesia of the Superior Laryngeal Nerve in Laryngeal Tuberculosis.

ACCORDING to A. DI CORE (*Rassegna internaz. di clin. e. ter.*, January, 1927, p. 27), since Sicard and Braun, in 1905, first proposed cocainization of the superior laryngeal nerve to relieve dysphagia in laryngeal tuberculosis, this method has remained almost exclusively in the hands of specialists. The dysphagia may be due to any of the following causes: (1) oedema, infiltration or ulceration of the epiglottis, arytenoids, or ary-epiglottidean folds; (2) painful rise during deglutition of a larynx of which the glottis or crico-arytenoid articulations are affected; (3) the passage of the bolus of food over an ulcerated mucous membrane or the constant rubbing of the posterior wall of the larynx against the pharynx. Di Core injects both superior laryngeal nerves with 2 or 3 c.cm. of a solution containing cocaine, morphine, antipyrine, quinine hydrochloride, and iodized glycerin; within about a quarter of an hour he obtains an anaesthesia of the larynx which allows the patient to swallow in comfort. The duration of the anaesthesia varies from a week to fifty days. In fifty cases it ranged from fifteen to twenty days, and in five, for some unaccountable reason, the treatment caused only a transient relief. Anaesthesia of the superior laryngeal nerve is considered a better method for relieving the dysphagia than resection of the nerve, first performed by Avellis in 1909, as the results of this operation are inconstant, anaesthesia is transient, and the death of the patient is sometimes accelerated thereby.

Obstetrics and Gynaecology.

457. Treatment of Cancer of the Body of the Uterus.

L. F. DRIESSEN (*Zentralbl. f. Gynäk.*, January 29th, 1927, p. 272) states that operable carcinoma of the body of the uterus demands surgical treatment consisting in abdominal total extirpation, but not Wertheim's operation. The earlier reports of 90 per cent. of cures were too optimistic, but 63 per cent. of cases of five years' freedom from recurrence has been attained in the author's experience. The results are better than those of radiotherapy. "Operability," however, is a very subjective term; it must be remembered that patients suffering from cancer of the body of the uterus are more often aged from 45 to 65 than from 40 to 45, and are frequently obese, with chronic cardiac, renal, or vascular disease. Accordingly the post-operative complications to be feared are not peritonitis, pyrexia, or other inflammatory conditions, but cardiac failure, bronchitis, or thrombosis. "Local operability," as gauged by technical facility of complete ablation of the carcinomatous area, approaches 100 per cent., but "general operability," assessed by careful survey of the patient's general condition, is very much less. In cases of poor operative risk Driessen has recently returned to the century-old method of intrauterine caustic applications; he uses sticks 8 to 10 mm. thick and 7 to 13 cm. long (according to the length of the uterine cavity), composed of zinc chloride 4 parts, zinc oxide 1 part, starch 3 parts, and water. The hygroscopic and caustic action of the zinc salts produces mummification of the endometrium and myometrium, with thrombosis in blood and lymph vessels, so that a cylindrical sequestrum may be removed within eight to fourteen days without narcosis. Radiotherapeutic applications are subsequently made. Similar "chemical extirpation" of carcinoma of the body of the uterus in certain cases has recently been advocated in America by Babcock and by Masson at the Mayo Clinic. In four out of five cases of cancer of the body of the uterus "locally operable," but appearing in patients suffering from heart disease, adiposity, diabetes, pyelonephritis, and chronic nephritis, Driessen has obtained, by the method described, cures lasting already from one to five years.

458. **Purpura Haemorrhagica in Pregnancy.**

H. W. HOFFENSTEIN and W. O. KLINGMAN (*Amer. Journ. Obstet. and Gynecol.*, March, 1927, p. 375) report a case of purpura haemorrhagica complicating pregnancy. It was similar to other recorded cases associated with pregnancy in the essential features of diminution of blood platelets, spontaneous bleeding from mucous membranes, purpuric skin lesions, delayed coagulation and increased bleeding time, non-retractility of the clot, and anaemia; but it differed in that it did not retrogress soon after labour. The patient, aged 30, with no history of familial blood dyscrasias or any serious illness except peritonitis following an abortion three years previously, had had a full term living male child eighteen months previously, when there was profuse post-partum haemorrhage but no purpura. About the fourth month of the next pregnancy purpuric spots appeared over the body and extremities; they increased in number and size as the pregnancy advanced, and there was some bleeding from the gums. Labour was rapid and there was no abnormal bleeding, but on the third day a septic temperature developed. In spite of blood transfusions the condition was always retrogressive, and, as oozing from the gums continued, splenectomy was performed immediately after a transfusion. The spleen was not enlarged and cultures showed a short chain streptococcus. The patient's condition after the operation was at first fairly good, with relatively high blood findings, but she died two days later. The necropsy showed generalized subcutaneous haemorrhages, oedema, and congestion of the brain and lungs with multiple haemorrhages in the latter, and petechial haemorrhages in the kidneys, ureters, and gastro-intestinal tract; there was also an acute necrotic endometritis.

459. **Pregnancy and Appendicitis.**

PORTES and SEGUY (*Gynécol. et Obstét.*, February, 1927, p. 114), while rejecting the view that the state of gestation renders women especially susceptible to acute appendicitis, assert that pregnancy plays an important part in causing acute recurrences in cases of chronic appendicitis. About half the cases of acute appendicitis during pregnancy are recurrences of this sort, so that it is prudent to counsel removal of the appendix before marriage in women who have previously had acute appendicular crises. Generalized peritonitis does not appear to be more common in the acute appendicitis of pregnant than that of non-pregnant subjects, but it is especially frequent in the "appendicitis of labour"; this, however, is usually an instance of antecedent appendicitis during pregnancy, aggravated or renewed by the phenomena of labour. On account of the special severity of the course which is likely to be taken by an attack of appendicitis at term, the authors dissent from the frequently expressed opinion that early operation is inadvisable for appendicitis during labour. Even when spontaneous cure has apparently followed an attack of acute appendicitis during pregnancy, the dangers associated with recurrence during labour are so great that the appendix should be removed as soon as the inflammatory conditions have settled down; the chances of the patient aborting as a consequence are little greater than those accompanying expectant treatment. The authors give details of three fatal cases of acute diffuse peritonitis accompanying acute appendicitis during labour or abortion.

Pathology.

460. **Surface Tension and the Action of Disinfectants.**

M. FROBISHER (*Journ. of Bacteriol.*, March, 1927, p. 163) has studied the effect on disinfectants of lowering the surface tension of their solutions. Using *B. typhosus* as the test organism, he found that the disinfectant action of phenol was lowered by the addition of 0.1 c.cm. of 1 per cent. sodium oleate solution, raised by the addition of 0.25 c.cm., and again lowered by the addition of 0.5 c.cm. There was thus an optimum concentration of sodium oleate which increased the disinfectant power. The reason why an increase in concentration of sodium oleate above the optimum lowers the disinfectant power is probably that a film of soap is deposited on the surface of the bacteria, which are therefore protected from the phenol. Similar experiments with similar results were made on hexylresorcinol. In another series of experiments ethyl acetate was substituted for sodium oleate. The addition of a suitable amount of this substance lowered the surface tension of phenol solutions from 70 to 57 dynes per centimetre, and considerably increased their disinfectant action. Working with the alkyl and the acyl resorcinols—substances which are at once disinfectants and reducers of surface tension—it was found that there was an inverse relation between the surface tension of the solution and the disinfectant power. It would appear, therefore, that the addition of suitable amounts of a surface tension reducer to phenol or hexylresorcinol increases the disinfectant power of these substances; and that in a series of substances which are themselves actively disinfectant, the disinfectant power is usually in proportion to their power of lowering surface tension. The way in which surface tension reducers act is probably (1) by increasing the penetration of the solution into minute crevices; (2) by aiding osmosis and diffusion; and (3) by favouring the adsorption of the disinfectant on to the surface of the bacteria.

461. **Pulmonary Embolism.**

E. HOLMAN, L. R. CHANDLER, and C. L. COOLEY (*Surg., Gynecol. and Obstet.*, March, 1927, p. 328) have investigated the process of inflammation following the experimental introduction into the jugular vein of emboli consisting of live tubercle and pyogenic bacilli. It was found that the tuberculous emboli started pathological changes in the pulmonary tissue resulting successively in anaemia, infarction, caseation, central softening, and abscess formation. The first appearance of a well defined abscess was on the twelfth day, whereas pyogenic emboli were found to produce abscesses within four or six days. The pathological changes due to pyogenic emboli included limited consolidation about the embolus, with early recovery; haemorrhagic infarction, with recovery or with central softening and abscess formation; and massive haemorrhagic consolidation and death. A relative lymphocytosis accompanied the tuberculous process, in contrast with a true polymorpholeucocytosis, which characterized the pyogenic processes. The emboli, as such, produced only slight changes in the pulse and the respiratory rates, which did not become elevated until the effect of the accompanying infection appeared after the lapse of twelve or twenty-four hours. Positive blood cultures were obtained as early as twenty-four hours after the introduction of pyogenic emboli, but this bacteriaemia was often only temporary and the animals recovered. The embolus introduced with the animal in the supine position usually followed the main current in the pulmonary artery, lodging in the left lower lobe fourteen times, in the right lower lobe eleven times, in the left upper lobe twice, and in the right upper lobe and the right middle lobe once each. The authors believe that this experimental method may assist in clearing up such questions as the effect of tuberculin in establishing immunity, the pathway of tuberculous infection, and the value of various therapeutic agents.

462. **Dissociation of Immunity from Hypersensitivity in Experimental Tuberculosis.**

M. NASTA (*C. R. Soc. de Biologie*, March 25th, 1927, p. 78) injected a number of guinea-pigs with 1/2000 mg. of bovine tubercle bacilli subcutaneously just in front of the shoulde The disease following this injection was very slow; eve after two and a half months the lesions were confined to th cervical, axillary, and tracheo-bronchial glands. The sam dose given subcutaneously into the thigh led to generalize tuberculosis with death in three months. At varying time after infection the animals were given a second injection either beneath the skin or into the peritoneum, a dose bein used far greater than that given in the first place. Contro animals which had not been previously infected received th same dose. It was found that the disease following the second inoculation was much milder than that in the contro animals. Thus certain animals had subcutaneous injections into the thigh of 10 mg. of living bacilli twenty-seven and forty days after the primary infection. At necropsies a month later it was noticed that the local abscess was either empty or contained caseous material practically free from tubercle bacilli, and that the iliac glands were only slightly affected; no tubercles were found in the spleen or liver, and only a few in the lungs. The control animals, on the other hand, showed a local abscess swarming with tubercle bacilli, and advanced lesions of the glands, spleen, liver, and lungs. Similarly in animals that were injected intraperitoneally with 50 mg. of living tubercle bacilli twenty-seven and forty days after the primary infection the progress of the disease was greatly retarded. In animals which received their second injection only fifty-four days after the primary infection a few caseous nodules developed; the spleen and liver remained intact. The control animals showed generalized tuberculosis. The author thinks that these experiments point to the establishment of immunity before hypersensitivity. In no case did Koch's phenomenon appear after subcutaneous injection, and in no case was there any evidence of toxaemia after intraperitoneal injection of the second dose. It is possible that these results depended on the slow evolution of the disease set up by the primary injection.

EPITOME OF CURRENT MEDICAL LITERATURE.

Medicine.

463. The Improved Prognosis in Pulmonary Tuberculosis.

A. J. COHEN (*Therapeutic Gazette*, March 15 h, 1927, p. 159) comments at length on the improved outlook in pulmonary tuberculosis which has been achieved by the combination of modern methods of treatment. Whereas fifteen years ago sanatoriums were limited to incipient cases the proportion of sanatorium beds allocated now to bed patients is stated as being 75 per cent., the hope of recovery of these cases having so greatly increased. As an illustration of the justifiability of such optimism he records the case of a girl, aged 11, who on admission to sanatorium had a large cavity in one lung, intestinal tuberculosis, enlarged cervical glands, carious teeth, vomiting, and diarrhoea. Her temperature ranged from subnormal in the morning to 103° in the afternoon, and she was very emaciated. After being kept in bed in the open for forty-three days it was decided to induce artificial pneumothorax, and gas was injected forty-six times at intervals of one, two, and three weeks. During treatment an effusion developed necessitating seventeen aspirations of fluid, amounting to a total of 150 ounces, which was positive for tubercle bacilli both by smear examination and by inoculation. She had seventeen intravenous injections of calcium chloride for the abdominal tuberculosis and 1,127 quartz lamp treatments for the abdominal and glandular conditions, with *x*-ray treatment also for the adenitis. Her teeth were put in order and she was kept in bed for eighteen months. Upon discharge, after two years in the sanatorium, she was above normal in weight, her digestion was good, she had no cough, and she looked the picture of health. She has remained in good health for eighteen months.

464. Cerebral Involvement in Measles.

F. REDLICH (*Zeit. f. Kinderheilk.*, February 14th, 1927, p. 178), who reports a personal case, illustrates the variety of nervous complications in measles by the fact that Boenheim, in 1925, out of 5,940 cases found that only 0.4 per cent. had such complications, of which six were examples of encephalitis. Redlich's patient was a child, aged 4, who shortly before the measles rash had faded developed signs of encephalitis. During the first few days the most striking phenomenon was drowsiness, accompanied by meningeal symptoms of moderate degree, myoclonus of the extremities, a mask-like expression, and amaurosis. At the beginning of the second week of disease the somnolence disappeared and choreic movements of the extremities and general restlessness developed, while the amaurosis persisted. On the fifteenth day of the encephalitis the clinical picture suddenly changed concurrently with the onset of left otitis media. The child became quieter, the choreic movements subsided, the vision returned, and within three weeks complete recovery resulted. Basal meningitis was excluded by the afebrile condition, the absence of well marked meningeal symptoms, such as Brudzinski's and Kernig's signs, as well as vomiting, and especially the normal cerebro-spinal fluid. The probability of the condition being due to a secondary toxic encephalitis was suggested by the onset occurring during the presence of the eruption, the mild course, and complete recovery.

465. Splenomegaly in Primary Syphilis.

R. LACROIX (*Thèse de Paris*, 1926, No. 254), who records nineteen illustrative cases in men aged from 18 to 57, maintains that enlargement of the spleen is a latent but constant symptom in the primary stage of syphilis. Owing to its being evidence of syphilitic septicaemia it is an important sign which helps to confirm the diagnosis, especially in recent cases in which the serum test is still negative. In association with the presence of other symptoms, such as the general appearance and induration of the chancre and concomitant adenopathy, it is of value in the differential diagnosis from other conditions, such as herpes. In mixed chancre in which a positive serum test is not obtained until late, and bacteriological examination is almost always negative, splenomegaly is a very important sign, and in association with other symptoms indicates the presence of syphilis and gives the patient the benefit of early treatment. Lacroix has found that by a systematic daily examination of the spleen, accompanied by daily clinical study of the chancre, he was able to declare that a primarily soft chancre had been transformed into a hard sore long before the serum test was positive, whereas the absence of splenomegaly in cases of septicaemia was shown to be an excellent proof of the absence of syphilis.

466. Acute Yellow Atrophy of the Liver.

M. PACKARD and H. ADLER (*Journ. Amer. Med. Assoc.*, March 19th, 1927, p. 892) report four fatal cases of acute hepatic toxic cirrhosis, with necropsies, the patients being aged respectively 27, 38, 16, and 4. They report that this acute degenerative process of the liver parenchyma may run an acute, subacute, or chronic course. In chronic cases an acute condition may supervene very exceptionally. Leucine and tyrosine were not found in the urine of any of the four patients. In one case there was some suspicion of arsenical poisoning, and another patient (aged 16) illustrated the fact that, in a case of supposed acute catarrhal jaundice, excited or irrational actions should lead to the suspicion that acute yellow atrophy is present. The authors add that in a doubtful case it is unwise to accept a diagnosis of acute catarrhal jaundice as being final until the patient has recovered.

467. Acute Dysentery and Uraemia of B. coli Origin.

P. MELNOTTE and A. FARJOT (*Bull. et Mém. Soc. Méd. des Hôp. de Paris*, March 24th, 1927, p. 361) observed in Morocco, during the summer of 1925, cases of acute dysentery accompanied by progressive uraemia which ran a rapidly fatal course. Microscopical examination of the stools, which were very frequent, haemorrhagic, and fetid, showed leucocytes and actively motile Gram-negative rods with the cultural characters of *B. coli*; amoebae were not detected. There was oliguria with slight albuminuria and a raised blood urea content of from 2 to 4.4 grams. Urine drawn aseptically from the bladder had the microscopical appearance of an eighteen-hour culture of *B. typhosus*, and the organisms on culture gave the characters of *B. coli*. All cultures from the blood were negative. With one exception all the cases terminated fatally in the course of a few days; treatment by emetine, stovarsol, and antidysenteric serum was without result. The necropsy showed numerous superficial, often confluent, ulcerations of the large intestine, especially about the rectum and the flexures of the colon; the small bowel was congested in places, but was not ulcerated. The kidneys were generally increased in size; the capsules stripped readily, but the cortical substance had a putty-like aspect on section. The patient's serum was negative for Shiga and Flexner cultures, and also for the *B. coli* isolated from the stools and urine.

Surgery.

468. Torsion of the Omentum.

A. POLLIDORI (*Arch. Ital. di Chir.*, March, 1927, p. 453) has collected 114 cases, including one under his own observation, of this condition, which was first described by Oberst in 1882. Lejars has described three varieties of torsion of the omentum, (1) torsion combined with an irreducible hernia; (2) torsion with an empty hernial sac; (3) torsion unaccompanied by a hernia, of which Pollidori's case was an example. Hernia is given as the most frequent cause of torsion of the omentum and is usually of the right inguinal variety. In only six cases reported by Vignard was the inguinal hernia on the left side; in another case the hernia was umbilical. Souligaux and Deschamps have recorded a case in which there was a parietal hernia following laparotomy. The great majority of cases of torsion of the omentum belong to Lejars's first two groups; there are only sixteen examples of the third group on record, including the one observed by Pollidori. The predisposing causes of torsion of the omentum may be classified as follows: (1) pathological thickening of the omentum due to chronic inflammation or the development of tumours; (2) adhesions between the omentum and the abdominal wall, or organs or tumours in the abdominal cavity, or the neck or fundus of a hernial sac. Torsion of the omentum must be distinguished from strangulated inguinal hernia, epiplocele, and appendicitis. If untreated the prognosis is usually unfavourable, except where only small portions of the omentum are involved, when adhesions or necrotic degeneration develop without giving rise to further symptoms. Of sixty-six cases collected by Lejars seven were fatal, but of these three died after the operation from accidental complications. Operation is

indicated in every case, and consists of removal of the twisted portion of the omentum. Polidori's case occurred in a woman, aged 38, in whom the diagnosis of acute intestinal obstruction of mechanical course was made before operation. Rapid recovery followed excision of the twisted part of the omentum.

469. Embolic Carcinoma of the Lung.

M. LOEPER and R. TURPIN (*Arch. Méd. Chir. de l'Appareil Respiratoire*, Vol. I, No. 5, 1926, p. 395) describe the pathological findings in a case of embolic pulmonary carcinoma. The disease started six years previously with the symptoms of gastric ulcer, followed by extensive phlebitis in the upper and lower extremities, and finally by malignant emboli of the lung. The primary gastric growth was a cubical-cell glandular epithelioma; the hepatic metastases resembled the characters of the original tumour. On the auricular side of the tricuspid valve was a nodule resembling a neoplastic graft the cancer cells of which were distributed in a support of young connective tissue and fibrino-leucocytic exudation on the way to becoming organized. Many arterioles were partially or completely obliterated by emboli of cancer cells and were adherent to the vascular periphery without inflammatory lesion. At the junctions of the interalveolar septa the capillaries were distended with red blood corpuscles and masses of neoplastic cells. The pulmonary alveoli showed cancerous and oedematous conditions distributed in relatively distinct areas; in some alveoli cancer cells with a few polymorphous leucocytes and red cells were free in the cavity of the alveolus, but more often the alveoli were completely filled with a homogeneous mass of malignant cells, though not adherent to the wall of the alveolus, the interalveolar septa usually remaining intact though yielding in places to the pressure of the growth. The alveolar wall did not react to contact with the cancer; no fibrino-leucocytic reaction was associated with the neoplastic infiltration. The lesions of the medium-sized bronchi consisted of invasion of the peripheral lymph vessels by malignant growth, and endobronchial agglomerations of neoplastic cells, pus cells, and red cells with mucus. The cavities of the small bronchioles were obliterated by masses of cancer cells. Discussing the nature of the obliterating phlebitis, the infective origin of which was excluded by negative blood culture and the absence of febrile symptoms, the authors consider that the presence of the nodule on the tricuspid valve and the endarteritis and venous lesions of the pulmonary parenchyma indicate that cancer cells are capable of growing on the inner lining of blood vessels and that the phlebitis may possibly be due to the same process.

470. Pulmonary Abscess.

M. SCHWARTZ (*Med. Journ. and Record*, November 17th, 1926) reviews eighteen cases of pulmonary abscess following tonsillectomy. In one case reported in detail a boy, aged 16 years, two weeks after tonsillectomy under local anaesthesia, complained of fever and weakness and of sudden pain in the right hypochondrium and lower right chest. The pain did not radiate, but was increased by motion, deep breathing, or coughing. He had some nausea, but did not vomit. Headache was absent, but malaise was marked. There were no symptoms referable to the gastro-intestinal, genito-urinary, cardio-vascular, or nervous systems. A family history of pulmonary tuberculosis, together with the physical signs in the chest, justified a tentative diagnosis of inflammation of the right pleura, probably tuberculous in origin. Some days later, changes in the physical signs and the appearance of temperature of the septic type, together with the results of investigation of the blood and sputum and an *x*-ray examination of the chest, justified a change in diagnosis to pulmonary abscess and interlobar empyema. Two weeks after admission *x*-ray examination showed a marked change in the condition of the right base; pleurisy was still present, and in addition there was an area of consolidation about two inches in diameter extending from the eighth interspace downwards. The upper border was sharply demarcated from the surrounding lung, and there was no evidence of breaking down in this area. A few days later liquefaction appeared to be occurring, and the patient expectorated large quantities of greenish-grey sputum. He continued to cough and expectorate profusely for the following two or three days, and after that the temperature became normal and remained so. A physical examination a few days later revealed evidence of a thickened pleura, and the breath sounds were distinct. Discussing the mode of onset of pulmonary abscess following tonsillectomy Schwartz states that it appears to be generally agreed that the condition is due to aspiration of infected material, and that the right lung is more often involved than the left owing to the bronchus on that side being larger and straighter. The condition may terminate by rupture into the bronchus thus being drained, by bursting into the pleura and causing empyema, or it may become chronic. Medical treatment should include bronchoscopic aspiration, together with the use of vaccines, rest, a high calorie diet, supportive medication, and a suitable posture. If these fail, then surgical intervention becomes necessary.

471. Treatment of Enlarged Prostate.

A. HINTZE (*Deut. Zeit. f. Chir.*, March, 1927, p. 450) records nineteen cases of enlarged prostate which were treated with injections of animal blood and *x* rays. The patients were all over 60, the average age being 71, and had suffered for several years from difficulty with micturition, which had gradually increased and led to complete retention of urine. The great majority of the patients were in the third stage of complete chronic retention, which required repeated use of the catheter. As the result of treatment all the patients recovered the power of spontaneous micturition, except three who had been in the habit of catheterizing themselves; the frequency of the act diminished by half, the jet of urine became more powerful, the pain completely disappeared, the residual urine fell to 30 to 50 c.cm., and the prostate became more or less considerably reduced in size. In most of the patients no recurrences took place. The injections, in doses of 2 to 5 c.cm., of ox, pig, or sheep's blood were made into each half of the prostate without anaesthesia. As a general rule the desired results were obtained after one to three injections or irradiations in the course of one to three months. In only a few cases were four or five injections and irradiations required.

Therapeutics.

472. Pituitrin in the Treatment of Post-operative Industrial Paralysis.

A. KRINSKY and E. C. STEIN (*Zentralbl. f. Chir.*, March 5th, 1927, p. 591), to illustrate the value of pituitrin in overcoming tympanites due to intestinal paralysis, report the case of a man, aged 64, who had suffered from abdominal pain for twenty years. After a sudden attack of severe pain in the right iliac fossa, with signs of obstruction, it was decided to operate, and as a preliminary a subcutaneous injection of physiological salt solution with 0.001 gram of strychnine was given. The abdomen was opened by a pararectal incision, under local anaesthesia. A violent cough caused the protrusion of a loop of deeply congested small intestine, and light ether anaesthesia was needed for its reposition. An abscess was found in the hollow of the sacrum; 20 c.cm. of a 20 per cent. oily solution of camphor was poured into the peritoneal cavity, two rubber drainage tubes were placed in the abscess cavity, and the wound was closed. Next day the condition was worse, there being increased tympanites with faecal vomiting. Atropine injections, glycerin enemata, gastric lavage, and hot applications all failed. There was no peristalsis. It was then decided to try intravenous injections of pituitrin in sodium chloride solution. After 100 c.cm. had been injected the breathing became easier, and the face was flushed. The injection was discontinued for five minutes, then a further 350 c.cm. was given. Colicky pains occurred, followed immediately by the sudden expulsion of much flatus and liquid faeces. That night the patient was free from pain and restlessness, without a narcotic, but next day the tympanites recurred, accompanied by vomiting and absence of peristalsis. Consequently the injections of 500 c.cm. of saline solution with 4 c.cm. pituitrin were repeated twice daily. Two days later a spontaneous evacuation occurred, and after this the patient did well.

473. Toxic Reaction from Luminal.

A. S. JACKSON (*Journ. Amer. Med. Assoc.*, February 26th, 1927, p. 642) reports six cases illustrating the toxic sequels of treatment by luminal; none terminated fatally, only temporary severe discomfort occurring. The characteristic signs and symptoms were the appearance of a generalized erythematous maculo-papular skin eruption accompanied by intense itching, fever, weakness, vertigo, and malaise. Prompt withdrawal of the drug, combined with the use of local sedatives, sufficed to clear up the condition. Jackson agrees that luminal is a valuable drug in the treatment of various nervous and mental disorders, including insomnia, associated with organic diseases such as toxic goitre, but thinks that its danger is not sufficiently appreciated.

474. Ergotamine as a Sympathetic Depressant.

C. DREYFUS (*Paris Méd.*, March 26th, 1927, p. 301) describes the inhibitory action of ergotamine on the sympathetic system. Hitherto, while a vagal inhibitor (atropine), an excitant (pilocarpine), and a sympathetic excitant (adrenaline) have all been known and used, the sympathetic depressant has been lacking. Rothlin showed experimentally that all

the effects of adrenaline, including vaso-constriction, acceleration of the heart, and [illegible] ected by the administration o[illegible] It has been used with grea[illegible] exophthalmic goitre, the tachycardia tremor and sleeplessness being much lessened in a few days. Other conditions in which ergotamine has been tried with success include glaucoma (where a hypodermic injection of ½ mg. reduced the intra-ocular pressure appreciably within an hour) paroxysmal tachycardia, migraine, disturbances of the menopause, and urticarias; but it is particularly in the non-operative and pre- and post-operative treatment of exophthalmic goitre that its value has been most clearly demonstrated. Three to five capsules of ergotamine, each containing 0.001 gram of the active principle, are given daily for about a week, followed by a rest of four or five days; after this the treatment is continued for another week, succeeded by another rest, and so on.

475. Interaction of Adrenaline and Colloidal Silver Preparations.

J. D. PILCHER (*Journ. Amer. Med. Assoc.*, March 5th, 1927, p. 720) has investigated the action of various silver preparations on adrenaline and finds that inactivation occurs within a few hours. The destructive action of protargol was much delayed by the presence of chloride, possibly owing to the precipitation of the silver. Pilcher recommends, therefore, that when the local effect of adrenaline on the nasal mucous membrane is required, it should not be used in combination with silver compounds; or, if the joint action is required, the mixture should be freshly made. Colloidal silver iodide and silver nitrate solutions were found to inactivate adrenaline less rapidly, and have, therefore, some advantage therapeutically.

Radiology.

476. Cholecystography.

E. A. GRAHAM (*Surg., Gynecol. and Obstet.*, February, 1927, p. 153) discusses the present position of cholecystography in the diagnosis of gall-bladder lesions, and the mechanism of emptying the gall bladder. The procedure provides a means of investigating the ability of the gall bladder to concentrate its contents as shown by an increasing density of the shadow and its ability to store bile as indicated by changes in size of the shadow. Not only is it useful in diagnosing cholecystitis, but more cases of stone can be recognized than is possible by ordinary *x*-ray examination, and by its means pericholecystitis, adhesions, anomalies, and abnormalities are revealed, and shadows can be definitely identified as being related to the gall bladder or not. Of a total of 1,246 patients so examined the gall bladder was removed in 147, the original *x*-ray diagnosis being confirmed in 143, showing a percentage of correctness of 97.28. Graham prefers the intravenous method to the oral as giving greater accuracy, and he considers phenoltetraiodophthalein as most satisfactory from the point of view of toxicity; he uses ampoules containing individual doses of the crystals as a safeguard against oxidation. After discussing the various theories put forward as to the mechanism by which the gall bladder empties he concludes that it does so through the cystic duct by the washing out of its contents by bile from the liver, by the elasticity or contractile mechanism of its walls, and by variations of intra-abdominal pressure. He adds that although the intrinsic muscular contractions are an important factor they act in conjunction with the others and are not in themselves the only mechanism of emptying.

477. Radiography of the Temporal Bone.

ACCORDING to P.-L. MAGNIEN (*Arch. Internat. de Laryngol.*, December, 1926, p. 1158) the temporal bone comprises three parts from a radiological point of view—the petrous, the mastoid, and the squamous portions. Examination of the squamous portion often reveals aberrant cells, especially those running up into the root of the zygomatic process and surmounting the middle-ear cleft. The author's studies of radiographs of the mastoid process in health and when inflamed have led him to the conclusion that the normal mastoid process is pneumatic or at least diploic in type and that the sclerosed or condensed type of mastoid is always the result of inflammation. In slight cases of acute mastoiditis the outlines of the cells are rather less distinct than usual. As the disease progresses there is a diminution in the density of the shadow thrown by the bone, and in empyema of the process the details of its structure disappear. The examination of the petrous bone is very important, since the detection of fractures may have considerable medico-legal value. The vertical and oblique fractures are the easiest to display; the horizontal ones need the special vertex-chin exposure of Hirtz. The apex of the petrous bone has been shown to be diseased in a number of cases of Gradenigo's syndrome. There may be a sclerosing osteitis or a rarefaction of the tip, with presumably surrounding inflammation of the soft tissues. Normally the lateral sinus does not give any impression, but in the cases of chronic osteitis it sometimes comes into view. Cushing and some French workers have shown radiographically the dilatation of the internal auditory meatus in cases of cerebello-pontile tumour. The localization of foreign bodies is facilitated by the introduction into the external ear, and in some cases the middle ear also, of an opaque substance such as bismuth, preferably on gauze. By similar methods the extent of a previous mastoid operation can be gauged.

478. X-ray Therapy in Malignant Disease of the Skin.

J. M. MARTIN (*Radiology*, March, 1927, p. 204) advocates the use of *x* rays in treating new growths of the skin, since they afford a reliable means of removing precancerous conditions without leaving an unsightly scar. Relief of pain is often obtained thus, while the prevention or control of metastases may be possible if treatment is started early. The chance of recurrence at the site of the former lesion is said to be no greater than after any other method. Notes and photographs of ten cases are given showing the satisfactory results obtained. For the local treatment of lesions he uses a 5-inch spark-gap and a current of 5 milliamperes, with five to ten minutes' exposure at a 10-inch target skin distance and a filter of 1/2 mm. of aluminium, while for the treatment and prevention of glandular metastases a 9-inch spark-gap, a current of 5 milliamperes for thirty minutes at a 12-inch target skin distance, with a filter of 1/2 mm. of copper, 1 mm. of aluminium, and four layers of leather are employed. Martin claims that most early lesions respond promptly, but that in many advanced lesions better results follow excision, actual cautery, or electrical coagulation, while the use of *x* rays combined with other methods is sometimes indicated.

479. Treatment of Vesical Neoplasms by Radium.

J. MCIR (*Journ. of Urology*, January, 1927, p. 53) describes a method of treating neoplasms of the bladder by means of removable platinum radon seeds, radiation being directed to the growth and to the tissues surrounding it in order to deal with the mitotic cells. Overlapping of the zones of radiation is avoided, and the radon seeds are easily removed through the cystoscope after the required radiation has been delivered, a thread being attached to each seed and serving also as a landmark by means of which other seeds can be spaced exactly.

Obstetrics and Gynaecology.

480. Treatment of Cancer of the Cervix in Pregnancy.

REEB (*La Gynécol.*, January, 1927, p. 1) states that increasing experience of radium therapy entails reconsideration of the principles of treatment of cancer of the cervix in association with pregnancy. In view of the satisfactory early results of treatment by radium and of the good remote results which follow Wertheim's hysterectomy combined with the Mikulicz drain, the following scheme of treatment is proposed. If the cancer is operable and the infant not viable, a surface application of radium to the cervix should be followed in a few weeks by wide hysterectomy, the fate of the foetus being ignored. With operable carcinoma and a foetus viable or approaching viability, the application of radium may be succeeded in four weeks by Caesarean section and wide hysterectomy. In cases of very advanced or inoperable carcinoma (whatever the stage of the pregnancy) removal of vegetations by the sharp spoon should be followed by superficial radium application. [illegible] ossible, until term, Caesarean section is [illegible] by subtotal hysterectomy, a further app[illegible] the cervical remnant by the combined abdominal and vaginal route, and later, if the neoplasm has regressed, by removal of the cervix. If the combination of carcinoma and gestation is not encountered until labour, it is suggested that if the general condition is good and the carcinoma appears operable, Caesarean section should be followed by Wertheim's operation. If the patient's condition is poor, or if she is very fat, or if the carcinoma is inoperable or of doubtful operability, Caesarean section should precede supravaginal hysterectomy or a classical Porro operation. An abdomino-vaginal radium application is made as soon as possible; if the tumour is smaller and the cervix is mobile, the latter may be removed vaginally a month later by means of Schuchardt's incision. Reeb adds that towards term Wertheim's operation is more simple than in the non-pregnant, since the isolation of the large vessels and the ureters is comparatively easy. On the other hand, the separation of the bladder is more difficult on account of the increased softness and vascularity of the

neighbouring tissues. The generalized softening of the pelvic tissues also hinders tactile appreciation of the limits of penetration by the growth.

481. A. P. RAMOS (*Gynécol. et Obstét.*, February, 1927, p. 125) believes that pregnancy renders cervical carcinoma much more susceptible to the influence of the gamma rays of radium. He relates the case of a 4-para, aged 29, who in the seventh month of pregnancy was found to have early operable squamous-cell carcinoma of the cervix. Two intracervical applications of 0.1 cg. of radium bromide for twenty-four hours were made. Death of the foetus was followed six weeks later by the onset of labour. Wertheim's operation was performed and *x*-ray treatment was given; the patient was well twelve months later. In a second case a 5-para suffering from operable carcinoma of the cervix was admitted to hospital with fetid lochia three days after rupture of the membranes. A living child having been removed by Caesarean section, Wertheim's operation was performed, followed by *x*-ray applications. Mikulicz's drain was used in this case. The author agrees with J. L. Faure and others that pregnancy, far from complicating Wertheim's operation, renders it more easy by reason of the increased softness and elasticity of the tissues.

482. Etiology of Rupture of the Uterus.

E. MORVAY (*Med. Klinik*, February 11th, 1927, p. 206) reviews a number of cases of rupture of the uterus, and concludes that rupture, whether spontaneous or following mild trauma during pregnancy or labour, is almost always due to several factors, of which local damage to the uterine wall from previous pregnancies or a Caesarean cicatrix is particularly important, especially if the uterine incision was high up in the fundus or sepsis delayed healing. He describes one case and mentions others in which the rupture started at a point in the uterine wall which had been damaged by recent curetting. In the majority of cases of spontaneous rupture the rent is in the fundus under an abnormally high placenta. Some cases occurring during labour follow internal manipulation or the use of instruments with slight general contraction of the pelvis, while malposition of the foetus and adhesions or stretching of the supports of the uterus also play some part in the etiology. Occasionally the rupture is due to mechanical stretching of the uterine wall over an ovum implanted in the interstitial end of a Fallopian tube. Many cases, however, remain unexplained because the histology of the condition has hitherto been neglected. Morvay describes in detail a case in which concealed accidental haemorrhage at the sixth month in a 4-para was followed by rupture after slight trauma. At the laparotomy, two days after the onset of symptoms, the macerated foetus was found lying in the abdominal cavity, and the placenta, which showed evidence of old and recent haemorrhage, was very firmly adherent to the uterine wall; the tear in the uterus involved the placental site and was 15 cm. long. On microscopic section it was found that the foetal trophoblast had penetrated the myometrium. In this case the rupture was apparently due to destruction of defective muscle in the uterine wall by abnormal proliferation of the placental cells.

483. Artificial Pneumothorax in Pregnancy.

A. DECAULNE (*Thèse de Paris*, 1926, No. 242), who records twelve illustrative cases, comes to the following conclusions. The occurrence of pregnancy in women treated by artificial pneumothorax does not aggravate the tuberculosis either before or after confinement. The performance of artificial pneumothorax during pregnancy produces an arrest of the tuberculous process and enables the pregnancy to pursue a normal course. Labour in such cases was always normal and did not appear to be more difficult than in women without any morbid antecedents. The child was always healthy, robust, and well formed.

Pathology.

484. Carbohydrate Metabolism in Malaria.

G. DE M. RUDOLF and R. G. B. MARSH (*Journ. Trop. Med. and Hyg.*, March 1st, 1927, p. 57) made the following observations upon carbohydrate metabolism in malaria, with special reference to the effect of insulin and glucose upon benign tertian malaria. The patients were cases of general paralysis and dementia praecox who had been inoculated therapeutically with the benign tertian parasite. It was found by the examination of single specimens of urine from each case that glycosuria was present in 0.9 per cent. of untreated general paralytics, but in 15.4 per cent. of those who had been inoculated. When the urine was examined repeatedly glycosuria was found in 90 per cent. of the treated paralytics. Blood sugar curves made in two cases after ingestion glucose tended to approach the normal more after inoculati with malaria than before. During malarial treatment t blood sugar varied inversely with the temperature. T subsequent rise in the blood sugar did not necessarily occ steadily, and the final curve after the temperature had fall might be higher than before the pyrexia. The administr tion of glucose during malarial pyrexia produced no obvio change in the objective signs, but apparently relieved t symptoms. No effect upon the parasites was observe Administration of insulin during malarial treatment had definite effect on the number of parasites, but in 60 per cen the fever terminated after insulin had been given. Relaps occurred, but differed from those following small doses quinine in showing a lower degree of pyrexia. The lowerin of the blood sugar did not appear to be the cause of th cessation of the fever. The authors regard it as inadvisabl to give insulin if there is a possibility of a rise of temperatur occurring shortly after.

485. Bacteriological Diagnosis of Pulmonary Tuberculosis in Infants.

P. F. ARMAND-DELILLE and J. VIBERT (*Presse Méd.*, March 30th, 1927, p. 402), in suspected pulmonary tuberculosis of infants where examination of the sputum was not possible, have had good results from washing out the stomach. An ordinary gastric tube was passed as long after a meal as possible, or immediately after the attack of coughing which occurred after sleep; by means of a large funnel 80 to 100 c.cm. of warm water was introduced into the stomach and quickly siphoned off. In this gastric washing bronchial secretion could often be recognized and examined for tubercle bacilli. In many cases where the bronchial secretion was only slight in amount it was found better to centrifuge the entire washing in three or four tubes for three-quarters of an hour. The deposits of the tubes were mixed in a porcelain dish; 30 c.cm. of water and 10 drops of soda lye were added, and the whole was heated over a gas burner for ten minutes, a further 50 c.cm. of water being added little by little and then allowed to cool. Three or four films were prepared from each washing and stained for tubercle bacilli. Out of 174 stomach washings 62 were not centrifuged, but were examined directly and gave only 6 positive results, and these were all from cases with definite physical and radiological signs, running a rapid and fatal course. From the examination of 110 centrifuged washings there were 34 positive results (30.9 per cent.). Of these, 13 confirmed the physical and radiological findings, 18 supported the radiological signs where physical signs were absent, and in 3 cases both physical and radiological signs were absent. Of the 56 negative results among the uncentrifuged series 38 had radiographical signs resembling tuberculous lesions, and 18 were tuberculous suspects owing to the nature of the environment. Among the 76 negatives of the centrifuged series only 15 showed radiological signs; the remaining 61 were examined on account of a history of possible contagion.

486. Preparation of Small-pox Virus in vitro.

A. CARREL and T. M. RIVERS (*C. R. Soc. de Biologie*, April 1st, 1927, p. 848) describe a method for the preparation of small-pox vaccine by cultivating the virus in a suitable tissue medium. The testicles of rabbits in which the virus had been growing were ground up in a mortar and suspended in saline so that each cubic centimetre contained 10,000 vaccinal units. (The unit is the smallest quantity capable of producing a characteristic pustule on intradermal injection into the rabbit.) A small quantity of this suspension was then inoculated into suitable tissues. The tissues used were the pulped skin, cornea, or brain of chicken embryos aged 6 to 14 days; the most favourable appeared to be embryonic pulp. The actual inoculation was made by mixing the testicular suspension with the tissue pulp, and leaving the mixture either in the incubator at 37° C. or in the ice chest for about twenty-four hours; flat circular flasks 5 or 8 cm. in diameter were used. The mixture of virus and tissue was placed in a coagulum of hen plasma contained in these flasks; the actual amount of medium used ranged from 2 to 16 c.cm. The cultures were washed every two or three days with Tyrode's solution, and were nourished with a dilute fowl embryo extract. After one to four weeks the coagulum and the tissues which they contained were withdrawn from the flasks and ground up in a mortar. Various dilutions were injected into rabbits intradermally. It was found that the cultures, which were inoculated with 25 to 250 units per cubic centimetre, contained after incubation, for a week between 10,000 and 100,000 units per cubic centimetre; the virus had evidently multiplied actively in the tissues of the cultures. The authors calculate that a single fowl embryo reduced to fine pulp should provide as much vaccine as a calf. They add that the technique is very simple, and could easily be used for the commercial manufacture of vaccine.

EPITOME OF CURRENT MEDICAL LITERATURE.

Medicine.

512. Diet Calculation in Diabetes Mellitus.

R. C. WINN (*Med. Journ. of Australia*, March 5th, 1927, p. 321) suggests a way of simplifying the dietetic treatment of diabetes mellitus without sacrificing any essential principles. By multiplying the patient's weight in pounds by twelve the number of necessary calories required in the diet is ascertained, and by using varying combinations of three "diet groups" (of 500, 600, and 900 calories) different diets containing any desired number of hundreds of calories can be prescribed. It is claimed as an advantage over the Lawrence line-ration scheme that the combination of "diet groups" is easy of calculation, and that the completed diet will never contain a smaller quantity than half an ounce of any foodstuff. On the diet prescribed very light work is allowed for a week, when the same diet is continued if sugar is still present though reduced in quantity, while if there is no reduction a diet of 200 calories less is prescribed, to be increased again if sugar-free at the end of the second week. If, however, the patient is not sugar-free by the end of the second week insulin should be given. If the urine remains free from sugar another increase of 200 calories may be made, and repeated each week until the patient is getting sufficient to be able to do light work. Winn contends that the islands of Langerhans can be best rested by such moderate reduction in diet without insulin in the majority of cases; insulin is added if sufficient food to give the strength for light work cannot be supplied otherwise.

513. Value of Exercise in Heart Disease.

E. FREUND (*Wien. klin. Woch.*, March 17th, 1927, p. 359) considers that exercise or mechano-therapy adapted to each case is useful in nearly all forms of heart disease to prevent atrophy of the cardiac muscle. In fully compensated cardiac lesions only the more strenuous forms of exercise, such as football and swimming, should be forbidden, while walking, skating, dancing, and gymnastic exercises are permitted and mechano-therapy is not required. Carefully graded mechano-therapy or passive exercise is very valuable for accelerating the patient's return to more active exercise during convalescence from decompensation, and in conditions of mild cardiac insufficiency such as are frequently associated with early mitral disease and obesity, or follow infectious diseases. The treatment can, if necessary, be applied with the patient in the recumbent position first. Freund advocates the following forms of mechano-therapy, either separately or combined, as benefiting the heart indirectly: centripetal massage of the limbs and passive movements to promote the drainage of lymph and blood from the extremities; breathing exercises to facilitate the return of venous blood to the heart by suction action within the thorax and compression of the liver by the diaphragm; while vibratory massage and tapotement of the precordium and interscapular region have a direct action on the heart. Exercises against resistance are also of value so long as dyspnoea is carefully avoided. Mechano-therapy is contraindicated in advanced failure of compensation, after recent cerebral haemorrhage, when there is danger of embolism, in endocarditis and severe cachexia. In arterio-sclerosis the amount of exercise or mechano-therapy required depends on the severity of the cases.

514. Typhoid Pleurisy.

T. LUCHERINI (*Rif. Med.*, February 28th, 1927, p. 211), who records two illustrative cases, states that pleurisy in typhoid fever is rare. It may occur at the onset of the disease and for a time disguise the character of the typhoid infection, when it is known as pleuro-typhoid; or, as more frequently happens, develop in the second week of the disease or even in convalescence. As regards the frequency of the complication Eichhorst, in 1,824 cases of typhoid, found pleurisy in 32 instances (2.5 per cent.); Sears saw it in 18 out of 1,056 cases (1.7 per cent.); Liebermeister met with it in 4 per cent., and Louis in 1.57 per cent. The character of the effusion may be serous, sero-fibrinous, haemorrhagic, or purulent. The pleurisy may be due to the sole action of the typhoid bacillus or to association with the ordinary [illegible] sometimes cultures of the fluid are s[illegible] cavity may be saccular, the fluid being purulent in one compartment and sero-fibrinous in another. In very rare cases the pleurisy may be bilateral or form part of a polyserositis. Cytological examination may show predominance of large mononuclear cells or more or less damaged neutrophil polymorphonuclears with a few mononuclears or lymphocytes or large endothelial cells, or red corpuscles. Lucherini's first case was in a boy, aged 14, who in the third week of typhoid fever developed pleurisy first on the right side and then on the left. The effusion was at first sero-fibrinous; later it became haemorrhagic, and finally purulent; death followed. Bacteriological examination showed the typhoid bacillus in association with *Staphylococcus pyogenes aureus*. The second case was that of a girl, aged 15, who developed a purulent effusion in the left pleura as the temperature was beginning to fall; she recovered. A pure culture of the typhoid bacillus was found in the pleural fluid.

515. Leprosy in Holland.

J. J. C. SCHREUDER (*Nederl. Tijdschr. v. Geneesk.*, March 12th, 1927, p. 1321), who records an illustrative case, remarks that autochthonous infection with leprosy is extremely rare in Holland, and that he has been able to find only three cases in Dutch literature. In each instance the patients had been infected by their brothers, who had contracted leprosy in the East Indies. In Schreuder's case also the patient had never been in contact with a case of leprosy until his brother, who was suffering from the disease, returned from the Dutch Indies. The patient took no precautions against infection, but rubbed ointment into his brother's sores with his unprotected hands and even wore his clothes and underlinen. Schreuder records the case to show that a leprosy patient may be a source of danger to his environment if the principles of hygiene are neglected.

516. The Dick Test.

J. A. TOOMEY, S. BRAUN, and I. HALPERIN (*Amer. Journ. Dis. Child.*, February, 1927, p. 197), as the result of their experience of the Dick test on more than 3,500 cases, came to the following conclusions: (1) The test is extremely specific, 1 c.cm. of the scarlatinal toxin being sufficient to make from 17 to 20,000 tests each of 0.1 c.cm. (2) The Dick test is the best method of ascertaining individual immunity or susceptibility to scarlet fever. (3) Control reactions do not ordinarily occur if the control toxin is boiled for twenty minutes. (4) The reactions that occur about the control mixtures in a small number of cases disappear in less than twenty-four hours. (5) As a rule persons with negative Dick tests have had negative reactions for as long as eighteen months.

Surgery.

517. Diverticulitis of Colon.

M. BALLIN (*Amer. Journ. Surg.*, February, 1927, p. 130) reports ten cases of diverticulitis of the colon, illustrating the great variety of symptoms to which the condition may give rise, and which, if better understood, would lead to the diagnosis of sigmoid diverticulitis much more frequently than is now the case. The condition is a sacculation, usually occurring between the mesentery and the epiploic appendages, caused by the mucosa being extruded through a weak spot in the muscularis. The sacculi are small, thin-walled, and often filled with calcareous faecal masses; the entrance is *minute*, so that inflammation and perforation easily occur. Such inflamed areas quickly become covered by the epiploic fat tabs of the colon, and the sigmoid easily becomes adherent to the neighbouring organs, giving rise to complications with bladder and ureteral symptoms or retroperitoneal abscess and intestinal adhesions. Clinical diagnosis rests mainly upon a history of colic in the left lower quadrant of the abdomen, the term "left-sided appendicitis" being descriptive of an attack. X-ray diagnosis is uncertain, since the diverticula may be filled with faecal matter so that no barium can enter; they are generally too small to be shown separately from the sigmoid, unless fresh plates are taken three or four days later when the sigmoid is empty of barium, and the small sacs can then be demonstrated. A severe case may present all the symptoms of an "acute abdomen," and inflammatory attacks may occur and quiet down again, the diverticulum emptying or becoming walled off. Even with abscess formation other attacks may occur if multiple diverticula are present. They may exist without giving rise to any symptoms, but constipation, a feeling of fullness, mucus in the stools, and aching in the left side, relieved by defaecation, may be due to chronic diverticulitis which may become

a factor in the formation of cancer. In chronic cases treatment aims at reducing the amount of faecal matter by a waste-free diet of meats, fish, eggs, and fats; vegetables are forbidden, and colonic irrigations are given to reduce the danger of hard masses stagnating in the diverticula. Perforations and abscesses require drainage, resection, anastomosis, or colostomy, as indicated by each individual case.

518. Thoracoplasty in Active Pulmonary Tuberculosis.

SEBRECHTS and DE WINTER (*Rev. Belge de la Tuberculose*, December, 1926, p. 246) and L. LOUTE (ibid., p. 272) advocate the more extensive employment of thoracoplasty in cases of pulmonary tuberculosis unsuitable for treatment by artificial pneumothorax. Although pneumothorax, when performed in the earlier stages, often prevents cavitation and pleurisy, and affords the necessary rest to the collapsed lung, it is useless in cases of pleuritic symphysis or of extensive pleural adhesions. Sebrechts and De Winter consider that in febrile cases, with extensive unilateral lesions and adherent pleurae, thoracoplasty should be employed as a substitute for pneumothorax. Hitherto its use has been very restricted. The authors report the case of a young married woman, aged 23, with tubercle bacilli in the sputum, who, six months earlier, had had a right pleuritic effusion. She had cough, dyspnoea, night sweats, and evening fever. Several attempts at insufflation showed extensive pleuritic adhesions. As no improvement followed, ten ribs were resected under local analgesia, with light chloroform anaesthesia for the deep resections. For two days the patient was comfortable, but on the third and fourth days the heart caused serious disturbance. On the twenty-third day healing was complete and the temperature was subnormal. The result was comparable in every respect with the best obtained by pneumothorax. Although the patient left hospital on the thirty-third day, her general condition remained very satisfactory nine months later; the thoracic deformity was very slight, but scattered crepitant râles were still heard in the right infraclavicular region. Loute strongly advocates extrapleural thoracoplasty in those cases of unilateral tuberculosis which are unsuitable for pneumothorax. He states that a previous minute clinical and radiological examination is essential, and considers that as the immediate results are very grave the operation should never be performed on debilitated patients, nor on those suffering from cardio-renal disease or diabetes. He refers to the very satisfactory results obtained by Sauerbruck—namely, 39 per cent. cured, 27 per cent. improved, 10 per cent. unchanged, 4 per cent. of patients died after operation, 20 per cent. died later from extension of the disease to the opposite side; but adds that the figures reported by other authors are scarcely so favourable.

519. Pseudo-Tumours of the Orbit.

V. CELADA (*Arch. de med. cir. y esp.*, March 12th, 1927, p. 363) states that the term "pseudo-tumour" was given by Birch-Hirschfeld to a condition presenting all the signs of an orbital tumour—namely, slow development, exophthalmos, diminution of the movements of the eyeball, increase of the orbital contents, and occasionally palpebral oedema, without any evidence of a tumour on microscopical examination. Three groups of pseudo-tumour are recognized—namely, (1) those which clear up spontaneously or under drug treatment, such as potassium iodide, mercury, or quinine, including cases due to syphilis or tuberculosis; (2) those in which no tumour is found on operation; and (3) those which resemble a tumour macroscopically but on microscopic examination show the appearances of a chronic inflammatory process. In the presence of an orbital tumour Williamson-Noble recommends the following investigations: examination of the urine for sugar; the Wassermann test, which should be activated if negative; the tuberculin test or deviation of complement; a blood count and determination of the coagulability of the blood; search for focal infection, including *x*-ray examination of the teeth and nasal sinuses; consideration of the possibility of Graves's disease; and an exploratory operation.

Therapeutics.

520. Malarial Treatment of General Paralysis.

H. CLAUDE, R. TARGOWLA, and M. CÉNAC (*Ann. de Méd.*, March, 1927, p. 169) report ten cases of general paralysis treated by malaria infection with beneficial results, subcutaneous injections of 3 to 5 c.cm. of blood from an infected, untreated patient being used. According to these authors most accidents in this procedure are slight and unimportant, but they enumerate the following conditions as contraindicating the treatment: advanced age, cardiopathy, nephritis, and morbid conditions such as tuberculosis. The plasmodium employed should always be of known virulence, the patient also being kept under strict observation during treatment. Before commencing the injections, a preparatory antisyphilitic treatment is advised, which should be stopped during the incubation and evolution of the malaria, and followed by a mixed treatment of arsenic and quinine. The benefits are an improvement in general health and an amelioration of neurological and mental symptoms; the authors emphasize the fact that many of their patients were enabled to resume professional activities.

521. A. FERRARO and T. C. C. FONG (*Journ. Nerv. and Ment. Dis.*, March, 1927, p. 225) report similar good results from this method of treatment, and state that even in unimproved cases beneficial results from the malarial treatment of general paralysis can be seen in the prolongation of life of the patient. Their method of administration was the intravenous injection of 2 c.cm. of the infected blood. Many authors have claimed that the rise in temperature is the real beneficial factor, the patient's response to this permitting a more successful fight against the disease. Other theories mentioned are an antagonism between the plasmodium and the spirochaete of general paralysis, the causation of an immunity reaction, and the establishing of a leucocytosis. Bunker and Kirby hold that a satisfactory outcome may depend, not only on the absence of irreparable anatomical changes, but also on the capacity of the patient to react to the stimulation.

522. V. ASKGAARD (*Ugeskrift for Laeger*, March 24th, 1927, p. 231) reports on the hospital treatment of 37 women and 160 men suffering from general paralysis and inoculated with malaria between October, 1922, and March, 1926. Of the 37 women, 6 were much improved, being rendered fit for work, 8 were improved, being rendered partially fit for work, 3 were improved but were still in hospital, 9 were unaffected by this treatment, and 11 were dead, 2 of the deaths occurring in connexion with this treatment. Of the 160 men, 25 showed no recurrence, 38 were improved and fit for work, 11 were improved but were still in hospital, 6 were improved but were still nursed at home, 50 were unaffected by this treatment, and 30 were dead, 8 of these deaths occurring in connexion with this treatment. With regard to the patients in the first category—namely, the 25 who showed no recurrence of symptoms—it was noteworthy that the disease had existed in most of them for less than a year. All the male patients were also treated with neosalvarsan in connexion with the malarial inoculation, but the women were not given specific treatment. The difference in the results among the men and the women was not great enough to warrant the drawing of conclusions as to the part played by the specific treatment of the men. The author also compares the fate of the subjects of general paralysis before and after the institution of malarial treatment at his hospital, but he gives percentages only and not the actual numbers. During 1917, 55 per cent. were dead after one year, 75 per cent. after two years, 85 per cent. after three years, and 86 per cent. after five years. In 1923, on the other hand, only 6 per cent. were dead after one year, 15 per cent. after two years, and 33 per cent. after three years. He concludes that the results of malarial treatment continue to be so encouraging that it is seldom warrantable to withhold it, and it is the more valuable now that recent research has greatly facilitated the early diagnosis of this disease.

523. Treatment of Tetanus.

S. O. FREEDLANDER (*Annals of Surgery*, March, 1927, p. 405) reports and analyses a series of 25 cases of tetanus which were treated by intravenous injections of antitetanic serum for comparison purposes. The wounds were exposed freely to the air by removing devitalized tissue, and a small amount of antitoxin was injected round them. Within the first twenty-four hours a total of 50,000 to 150,000 units was injected intravenously in three to five doses, and thereafter a daily intravenous injection of 15,000 to 150,000 units was given. This daily routine was maintained into convalescence, sometimes for as long as twelve to fifteen days, depending upon the muscular rigidity; in the later cases the injections were not continued so long. Every six hours morphine was given hypodermically and chloretone by the rectum. Food and fluids were pressed upon the patients. Of the twenty-five patients treated in this routine way, eleven had an incubation period of less than ten days, with a mortality rate of 45.5 per cent. Six patients died before sufficient antitoxin could be administered; if these are excluded, the mortality rate becomes 12 per cent. It is concluded that the intravenous administration of tetanus antitoxin in large doses has some therapeutic value. The author hopes that others will record series of cases treated systematically by antitoxin in different ways so that their results may be compared.

524. **Nasal Instillations of Oily Preparations.**

L. BECO (*Le Scalpel*, March 12th, 1927, p. 242) criticizes statements about the danger of using oily preparations for nasal instillations. He refers to the report by Laughlen of five cases, in three of which nasal instillations of mentholated paraffin had been administered for a long period, and in two liquid paraffin as a laxative. These patients died of pneumonia, and necropsies revealed areas of bronchopneumonia. Microscopical preparations showed in one case a polynuclear leucocytosis, such as is found in septic conditions; in another, mononuclear cells containing vacuoles, which by appropriate staining proved to be oil droplets, were seen; and the remaining cases gave mixed septic and macrophagic pictures. Beco draws attention to the facts that all the cases were asthenic, that large doses had been employed, and that the oil might have carried infection from the respiratory passages to the lungs. He maintains that there is *no danger to be feared* from the use of these oily preparations if they are administered carefully and in proper doses, and that their employment is indicated in certain infectious fevers in order to guard against auricular and pulmonary complications.

525. **Oxygen Therapy in Pneumonia.**

J. H. EVANS (*Anesthesia and Analgesia*, April, 1927, p. 57), who records twelve illustrative cases, recommends higher percentages of oxygen in the treatment of pneumonia than have hitherto been advocated, and urges that it should be used earlier in the disease instead of waiting till it is almost certain that the patient is going to die. Of the twelve patients six recovered, although five of the six were apparently doomed. Three of these received as nearly as possible 100 per cent. oxygen from twenty to twenty-four hours out of the twenty-four for several days. In the case of two patients who recovered oxygen was started a few hours after the onset of the pneumonia. The six deaths occurred in patients who were moribund when the oxygen was started.

Dermatology.

526. **X-Ray Treatment of Lichen.**

M. NIJKERK (*Nederl. Tijdschr. v. Geneesk.*, February 12th, 1927, p. 848) who records eight cases of lichen in patients aged from 22 to 63 treated by x rays, states that Gouin in 1925 introduced a new treatment of lichen, consisting in interscapular x-ray treatment of the sympathetic at the level of the fourth and fifth dorsal vertebrae. In cases of generalized lichen Gouin saw this treatment cure the lesions on the chest, arms, thighs, and legs. In lichen corneatus universalis lumbo-sacral irradiation at the level of the third lumbar vertebra was required, in addition to the interscapular application, to cure the lesions on the feet. Lichen of the mucous membranes associated with the skin lesions was not affected by the method. In early cases the treatment was successful in about a month; in more chronic cases the lesions took from one to one and a half months to clear up. In some patients there was increased itching and redness of the lesions within twenty-four hours of the irradiation, but a few days later improvement set in and the papules disappeared, leaving pigmentation. Nijkerk irradiated the interscapular and lumbo-sacral regions like Gouin, but employed smaller and repeated doses; in seven out of eight cases complete recovery followed in from one to ten months. The success of the treatment is attributed to alterations in the composition of the blood, such as diminution of the calcium ions and increase of the potassium ions, changes in the autonomic nervous system, and endocrine modifications.

527. **Oïdiomycosis of Nails.**

J. A. SCOTT (*Brit. Journ. Derm. and Syph.*, March, 1927, p. 119) describes a case of oïdiomycosis of the nails of two years' duration in a single woman, aged 35. The infection commenced in the nail of the right thumb; it was followed a few months later by a similar affection of the nails of the right index finger and the left middle finger. Except for slight pain for a short time in the nail of the right index finger the condition was painless and the disease affected only the middle third of the nails, appearing as greyish-yellow patches under the nails, which were very little thickened and only slightly raised from the nail bed. All the other nails were healthy; there were no lesions round the growing edge of the nails and no skin lesions of the fingers. Scrapings showed the presence of [illegible]. Sabouraud advises remo[illegible]ainting with 1 per cent. io[illegible] rectified spirit, or wet dressings at night with a solution of iodine 1 gram, potassium iodide 2 grams, and distilled water 1,000 grams, and during the day the application of an ointment of benzoic acid 1 gram, zinc oxide 1 gram, and vaseline 30 grams; in resistant cases 1 per cent. chrysophanic acid in lard is recommended. The patient refused to have the nails removed, but considerable improvement followed treatment applied after scraping away the nails down to the infected parts. She suffered from vague gastro-intestinal troubles and was in low general health, which may have resulted from the same cause, since it is recognized that oïdia, when they invade the body, may produce serious general disorders. Scott considers that the possibility of the condition being a port of entry for the systemic disease renders its recognition and treatment important.

528. **Pityriasis Rosea.**

R. S. WEISS, C. W. LANE, and W. A. SHOWMAN (*Arch. Derm. and Syph.*, March, 1927, p. 304) have made a critical study of 380 patients suffering from pityriasis rosea. In 56.6 per cent. of the cases the disease was found to occur between the ages of 10 and 30, women being attacked twice as frequently as men. The beginning and end of the year were the periods of greatest case incidence, the height of the curve being in January. The primary patch was most often noted on the anterior wall of the thorax. The classical macular type occurred in 76.1 per cent. of cases. Itching was a prominent symptom in 26.8 per cent. of the patients. The authors believe that in time a parasitic factor will be discovered. As a rule immunity to another attack is observed, although second attacks sometimes occur; cases of relapse have been reported.

529. **Creeping Disease.**

E. CAZENAVE (*Ann. de Derm. et de Syph.*, March, 1927, p. 164) describes a case of creeping disease, sometimes known as larva migrans. A girl, aged 19, who spent a holiday amongst pine woods and on the seashore, going about with bare feet, first noticed an itching area on the inside of the right foot on September 7th; two days later some vesicles were seen and more appeared on successive days. On September 18th the area was cauterized, and for two or three days the itching ceased but soon recurred. Balsam of Peru gave some relief, but on October 9th the area had increased in length to 1½ inches. On raising the cutis straw-coloured serum escaped, but no blood. Finally a compress soaked in xylol was applied for ten minutes, and the area and furrows were touched with the cautery at dull heat. This cured the disease, and there was no recurrence. The larva was not discovered in this author's case.

Obstetrics and Gynaecology.

530. **Tubo-uterine Implantation.**

ACCORDING to G. COTTE and P. BERTRAND (*Gynécol. et Obstét.*, March, 1927, p. 182) implantation of the Fallopian tube into the cornu of the uterus was first performed by Watkins in 1899; ablation of an adenomyomatous nodule of the isthmic portion had preceded the implantation. The adnexa of the opposite side had previously been extirpated, and the fact that a few months after the first operation the patient had a uterine abortion showed that the anastomosis had retained its permeability. The second observation was published twenty-two years later by H. N. Shaw, and the present authors record the first three cases published in France. In their cases post-operative permeability of the anastomosis was proved by radiographic examination after intrauterine injection of lipiodol, five months after operation in one case and fifteen days in the other two. Of twelve other cases summarized from the literature the tubal permeability after operation was demonstrated in three by Rubin's insufflation method. Of the total of fifteen cases alluded to in this paper, no fewer than thirteen have been operated on within the last four years. Nevertheless six pregnancies have followed, of which two are known to have resulted in live birth at term, so that the results of this conservative operation appear to be encouraging.

531. R. MICHAELIS (*Zentralbl. f. Gynäk.*, March 26th, 1927, p. 779) alludes to four pregnancies and three live births following thirty-five to forty tubal implantation operations. He gives details of a hitherto unpublished case of live birth at term after bilateral tubo-uterine implantation. The patient, a recently married woman aged 34, showed signs during her first pregnancy of acute pulmonary tuberculosis, for which, on medical grounds, the induction of abortion was advised, combined with sterilization; Caesarean section was preceded by ligature and division of the Fallopian tube on both sides. A year later the tuberculous process had ceased to be evident, and the patient, who now felt well, was anxious to have a child. At a second laparotomy the impermeability of the

tubes was demonstrated and tubal implantation was performed on each side according to the Strassmann technique. The patient became pregnant within six months, and was delivered at term of a living child weighing 3¼ kilograms. The indications given by Strassmann for tubo-uterine implantation are: (1) ectopic pregnancy in the isthmic or interstitial portion of the tube; (2) adenoma of the tubal angle or *salpingitis isthmica nodosa*; (3) *correction of a previous* sterilizing operation on the tube. The possibility of pregnancy is much greater in cases where the operation has been performed for non-inflammatory morbid conditions of the tubes.

532. Pregnancy and Heart-block.

W. DRESSLER (*Wien. Arch. f. Inn. Med.*, March 15th, 1927, p. 83) cites Mackenzie's conclusion that sinus arrhythmia and extrasystoles are of little importance in pregnancy. Auricular fibrillation is a much graver complication, especially when it is associated with mitral stenosis. Dressler describes two cases of primiparae who, in spite of symptoms of serious heart-block, passed through pregnancy and labour without any untoward occurrence. The first patient, aged 35, had suffered from frequent syncopal attacks. For twenty years she had had symptoms of partial or complete heart-block associated with the Stokes-Adams syndrome. The other patient, aged 22, had had frequent syncopal attacks after influenza, five years previously. For a long time she had felt weak, but improved after the commencement of pregnancy. The heart was slightly enlarged and the cardiac sounds were impure; the pulse rate was 40. The confinement and puerperium were entirely normal, but on her discharge from hospital an electro-cardiogram showed complete heart-block. On the other hand, Freund has reported the case of a patient, aged 36, who had signs of mitral regurgitation and possibly stenosis. She had numerous syncopal attacks during her seventh pregnancy; a severe uterine haemorrhage necessitated induction of premature labour. A year later she was again five and a half months pregnant, with almost continuous haemorrhage from the commencement of pregnancy; she was very anaemic. Shortly after admission the patient had an eclamptic seizure and died. The necropsy revealed mitral incompetence and old and recent endocarditis; pathological changes in the bundle of His were demonstrated. It is probable that the syncopal attacks during the seventh pregnancy were due to the Stokes-Adams syndrome. Reviewing the present state of knowledge in these cases, Dressler concludes that every woman who exhibits even slight symptoms of the interruption of the bundle of His should be kept under most careful observation; the existence of any extensive myocardial disease must be regarded as absolutely prohibiting the risks of pregnancy and parturition. He thinks that a more complete heart-block may not produce perceptible reduction of the functional capacity of the auriculo-ventricular bundle; partial heart-block does not therefore necessarily forbid the patient running the risk of pregnancy, provided that she is kept under observation, so that pregnancy may be terminated if signs of extensive myocardial disease appear. He adds that in treating these cases of partial heart-block the possibility of the onset of Stokes-Adams syndrome during pregnancy or labour must be always remembered, as this would indicate that pregnancy should be terminated in the interest of the patient.

Pathology.

533. Small-pox Immunization and Rabies.

B. BUSSON (*Wien. klin. Woch.*, April 7th, 1927, p. 449) had previously reported that a freshly acquired small-pox immunity gave a definite protection to guinea-pigs against a usually fatal infection with rabies virus, and the question arose whether this was due to some specific interrelation of the two viruses, or was only the result of a non-specific raised resistance caused by the previous vaccination. Nine guinea-pigs were inoculated with 1/2 c.cm. of a thick emulsion of rabies virus, and on the following day each was vaccinated. Within fourteen to seventeen days eight had died of rabies and only one survived. Eight other guinea-pigs were satisfactorily vaccinated and five days later were strongly infected with rabies, of which seven died; in the controls three out of four guinea-pigs and all of six rabbits died with rabies. Of fourteen guinea-pigs vaccinated with glycerinated lymph and twenty days later inoculated with rabies virus, ten died and four were well at the end of a month. Of two guinea-pigs subsequently inoculated with large doses of vaccine lymph and after fourteen and sixty days respectively infected with rabies, both remained free from symptoms of rabies for a month. These results show that vaccination during the incubation period of rabies infection in no way changes or influences the period of onset or the character of the rabies. The onset of rabies infection is, however, delayed in guinea-pigs previously vaccinated and already immune from small-pox.

534. Experimental Atherosclerosis.

S. SHAPIRO (*Journ. Exper. Med.*, April 1st, 1927, p. 595) has found that in rabbits thyroidectomy, splenectomy, and gonadectomy augment hypercholesterolaemia, and accelerate the development of atheromata of the aorta. The deposition of cholesterol within the aortic intima starts the cellular alterations which result in atheroma. The relation of the spleen to the reticulo-endothelial system and its function in the destruction of old and the formation of new erythrocytes indicate the possibility that this organ not only stores but utilizes cholesterol. Hypercholesterolaemia has been found to follow splenectomy. Little is known about the relation of the gonads to cholesterol metabolism, but a synergistic functional association appears to exist between the sex-glands and the thyroid, and on this may depend the importance of the gonads in cholesterol metabolism. The thyroid plays the essential part in the metabolism of fats and fat-like substances, including cholesterol; thyroid insufficiency over long periods is accompanied by hypercholesterolaemia, the increase in the blood cholesterol being directly proportional to the degree of thyroid insufficiency. Suprarenal insufficiency does not aid in cholesterol deposition, and may even exert an inhibitory influence on the development of atheroma. Atherosclerosis is rare in individuals with lymphatism and other conditions of lymphoidal overgrowth. Shapiro's findings indicate that the deposition of cholesterol within the intima of the aorta initiates the formation of atheromata, and any condition—such as hypercholesterolaemia or mechanical forces—which predisposes to such precipitation favours the development of atheromatosis. He adds that this view agrees with the findings of Aschoff and of Wacker and Hueck.

535. Calcium Metabolism in Calcareous Gout and Scleroderma.

REPORTING their findings in a case of scleroderma, M. WOLF and A. VALLETTE (*Rev. de Méd.*, 1926, No. 9, p. 1121) discuss in detail the subject of calcareous deposits in the body. A woman, aged 55, suffered from calcareous nodules on various parts of the body, which on analysis proved to consist of pure phosphate of lime. They were comparable with the tophi of gout, excepting that they contained neither cholesterin nor uric acid, and resembled those found in calcareous gout. Clinically, the authors divide these cases into an inflammatory type, characterized by calcifications at the site of small abscesses or necroses, and a non-inflammatory type, which occurs, with perceptible differences, according to age. In young patients the trouble has the appearance and clinical characteristics of a general affection, and pathologically is clearly due to an endocrine derangement, a diathesis being also indicated. In old subjects there exists a predisposition to sclerosis and tissue calcification, as in atheroma of the blood vessels. The authors consider that the pathology of this disease is concerned with endocrine modifications, and that possibly the same endocrine factor acts in both old and young subjects. The blood calcium is increased, but it is unknown whether this is due to an actual excess or to a diminished solubility of the calcium in the blood. Treatment of this condition has been unsatisfactory. In cases with a history of congenital syphilis some amelioration has followed specific treatment. In their own case Wolf and Vallette performed sympathectomy at the cervical ganglia. This produced a slight retrocession of the scleroderma of the face and neck and a marked lessening of the pain, but there was no change in the lesions in other parts of the body. They recommend in all cases ultra-violet irradiation, and state that this often gives appreciable results.

536. The Serum Calcium Content in Skin Diseases.

G. H. PERCIVAL and C. P. STEWART (*Journ. Derm. and Syph.*, April, 1927, p. 144) have ascertained the calcium content of the blood serum in a variety of skin diseases, the method of estimation used being that devised by Kramer and Tisdal. The average was between 9.2 and 10.2 mg. per 100 c.cm. of serum. The figures recorded agreed with those of previous observers, and on the whole there was no great departure from the normal content. No clinical benefit was found to follow the administration of parathyroid extract in various conditions, including psoriasis, acne pustulosa, and lupus erythematosus, although the serum calcium was definitely increased. The authors conclude that in skin diseases disturbance of the calcium metabolism has no etiological relation to the onset or course of the various pathological processes.

EPITOME OF CURRENT MEDICAL LITERATURE.

Medicine.

537. Incidence of Late Forms of Syphilis.

C. BRUHNS (*Med. Klinik*, February 18th, 1927, p. 233) combats the view, expressed by a number of workers recently, that the incidence of such late manifestations of syphilis as aortitis, tabes, and general paralysis of the insane has been increased by the intensive treatment with salvarsan in the early stages which has been practised in recent years. He states that since the undisputed increase in aortic syphilis during recent decades began before the use of salvarsan became general in 1910, and aortic syphilis takes fifteen to twenty years to develop after infection, the next few years will show what effect early treatment has had on this late form. Shortening of the incubation period of aortitis and the late nervous manifestations has not been demonstrated, nor has there been any marked increase in the number of cases of general paralysis as a result of the usually incomplete courses of injections given during the earlier years of the salvarsan era. Though metasyphilis has apparently increased in spite of the more extensive use of mercury, the conclusion is not justified that more intensive salvarsan treatment will similarly be followed by an increase in metasyphilis, more especially since complete cure of the early stages is much more readily obtained with systematic salvarsan treatment. That intensive salvarsan treatment has certainly greatly diminished the spread of syphilis by shortening the infective stage was shown in a report by Jadassohn based on the findings of a number of dermatologists in various countries. It is therefore the best general prophylactic against aortitis and other late forms of syphilis, even if it does not ultimately prove entirely effective in all cases.

538. Active Immunization in Scarlet Fever.

J. MUNK and M. DE KORTE (*Nederl. Tijdschr. v. Geneesk.*, January 1st, 1927, p. 132) record an outbreak of 22 cases of scarlet fever in an asylum for mentally defective children. Of the 52 other inmates only 12 gave a positive Dick reaction. One of the latter developed scarlet fever the day after the test and the whole of the lower arm became swollen and red. Of the remaining 11, 5 were inoculated with Dick toxin and 6 received no immunizing injection. Five weeks later 3 of the 5 gave a negative Dick reaction, while 2 were still positive. On the other hand, of the 6 positive cases which had not been injected 5 had become negative and only 1 was still positive. This indicates that in a community where an infectious disease is prevalent susceptible persons may become immune without showing any signs of disease. The possibility of mild attacks could be excluded, as these children were kept under close observation. Another conclusion drawn is that it cannot be said with certainty that the children who had been actively immunized owed their negative reactions to the injections.

539. Solitary Living as a Cause of Scurvy.

ED. MEULENGRACHT (*Ugeskrift for Laeger*, March 3rd, 1927, p. 165) has, during the past two years, observed as many as eight cases of scurvy in patients admitted to his hospital under a variety of diagnoses, none of which was that of scurvy. The patients were middle-aged or elderly bachelors or widowers, and the most prominent manifestations of the disease were large extravasations of blood in the skin and subcutaneous tissues. The colour of these extravasations was much variegated—red, blue, violet, green, and yellow alternating in one and the same limb according to the age of the haemorrhage. In some cases there were also haemorrhages into the muscles, which felt tense and hard. When these haemorrhages occurred in the neighbourhood of joints there were effusions into them. In almost every case there were also numerous tiny haemorrhages around hair follicles, and both the large and the small haemorrhages were most common in the legs. In most cases there was a typical gingivitis with loosening and tenderness of the teeth. There was not a trace of gingivitis in the patients who had already lost all their teeth. Most of the patients were anaemic, but the rate of coagulation of the blood was normal. There was slight jaundice in some cases, and the patients were emaciated and mentally and physically debilitated, looking tired and apathetic. All had lived, or rather existed, in lodgings by themselves, not having access in most cases to the kitchens of the houses in which they lived. With only an oil or spirit lamp, or with not even these elementary accessories, they lived on bread, butter, margarine, fat, salted or smoked food, cheese, and beer or coffee. They had not the money, or would not take the trouble, to provide themselves with fruit and vegetables, and they were thus living on a diet containing practically no antiscorbutic C vitamin. In six of the eight cases the symptoms developed between March and June. Recovery was rapid under an ordinary mixed diet which included plenty of vegetables and fruit. The diagnosis under which these patients were sent to hospital was phlebitis in two cases, the haemorrhagic diathesis in two, heart disease in two, anaemic jaundice in one, and peliosis rheumatica in one. The author concludes that this cause of illness may be much more common than hospital and general practice records suggest, the true state of affairs being overlooked and the wrong diagnosis made. Also, for every such fully developed case of scurvy there must be many less definite and obvious.

540. Sickle-cell Anaemia.

H. S. ALDEN (*Amer. Journ. Med. Sci.*, February, 1927, p. 168) describes this severe anaemia as a familial and hereditary disease of negroes, occurring in both sexes, and characterized by the presence of peculiar sickle-shaped erythrocytes in the blood, a moderately severe anaemia, a varying degree of jaundice, physical and sexual under-development, a general glandular enlargement, and ulcers of the legs. In the active form the sickle cells are present in the circulating blood, but in the latent type the cells only become sickle-shaped after standing in a closed chamber for some hours. At the necropsies on patients dying from this anaemia there is found a small, contracted, fibrotic spleen with large numbers of old and recent haemorrhages and evidences of increased blood destruction in and about the Malpighian corpuscles. The bone marrow shows marked diminution of fat with a large number of sickle-shaped and curiously formed cells, red blood cells, and, in some cases, a rather marked hyperplasia. Since 1910 there have been reported 106 cases of this disease, and Alden now adds two further cases. There were many points of similarity with haemolytic jaundice, and an erroneous diagnosis, as of syphilis or acute appendicitis, is possible. In one case, for three months the ulcers on the legs were considered syphilitic; in the other, sudden abdominal pain and distension, due probably to a splenic haemorrhage, was diagnosed as acute appendicitis. Sickle-cell anaemia is only temporarily relieved by medical treatment and transfusion. Splenectomy has been suggested, but it has not been attempted. The prognosis is bad, the disease pursuing a gradually downward course, and the patients rarely living beyond the age of 30.

541. Conjugal Tuberculosis.

FROM an analysis of 1,491 patients admitted to the chest department of the Jefferson Hospital, N. BLUMBERG (*Therapeutic Gazette*, February 15th, 1927, p. 81) found that, among 814 married patients with tuberculous disease, a history of tuberculosis in the marriage partner was obtained in 54 instances. The percentage of patients who had apparently contracted this disease from their husbands or wives was approximately 6.6. If 17 cases in which there was a family history are deducted, the figures drop to 37 cases, or 4.5 per cent. From these investigations the author concludes that conjugal tuberculosis is not common; that contact infection in married couples is less than the contact rate for the general population; that, if there is no distinct family history, the individual is not so likely to show infection; and that the majority of individuals have developed an infection during childhood which has been cured, and are not so likely to become infected or reinfected later in life.

542. Tuberculosis Indicated by Slight Menstrual Pyrexia.

S. TRENTINI (*Il Policlinico*, Sez. Prat., March 7th, 1927, p. 343) discusses the appearance of slight pyrexia at or immediately before the menstrual period. His observations are based on a study of 35 tuberculous women—the average rise of temperature observed was from 4 to 8 tenths of a degree. He suggests that when a woman, normally [illegible] a rise of temperature in her pre-menstrual period the possibility of tuberculosis should be considered. When the rise of temperature occurs in early tuberculosis it usually appears one or two days before the menstrual period and disappears quickly when the flow is established. Probably the rise in temperature is due to the toxic state of the blood which precedes menstruation. If this pre-menstrual temperature

persists beyond the duration of the period it usually indicates some specific tuberculous activity. In the first type of temperature the fever suggests a latent tuberculous focus and indicates a simple thermic instability in a woman. In the second group where the temperature persists it is more likely to be the expression of a tuberculous focus in process of evolution causing some toxaemia while the powers of defence in the body are lowered by the process of menstruation.

523. Massive Collapse of the Lung.

L. R. SANTE (*Radiology*, January, 1927, p. 1) discusses massive collapse of the lung, and reports three unusual cases. He considers it a clinical entity, and states that it must not be confused with congenital atelectasis. Massive collapse is characterized by sudden shrinkage of one or more lobes of the lung without bronchial obstruction or other apparent cause, previous aeration having been good. It occurs most commonly after abdominal operations, wounds, and other traumatic conditions, such as fractures of the pelvis. Sometimes, however, very trivial injuries may be followed by this condition. X-ray examination shows a dense consolidation corresponding to the lobes affected and resembling that seen in lobar pneumonia, but the narrowing of the chest on the affected side, approximation of the interspaces, elevation of the diaphragm, and the mediastinal displacement render the diagnosis simple. With reference to etiology it is suggested that some traumatic or toxic injury acts upon the vagal supply and so the bronchioles collapse; their walls cohere and the lung rapidly contracts owing to the absorption of alveolar air by the circulating blood. In one of the three cases described the collapse did not occur until thirty-three days after an operation, and the septic condition present was considered more likely to be responsible. Further, there was slight deviation of the trachea before consolidation. The chest wall assumed its normal position when it was opened at autopsy, and the lungs did not completely fill the cavity. In the second case there was nothing in the past history to account for the onset of collapse; expansion of a large part of the lung was re-established by merely rolling the patient over for radiographic examination. In the third case there was no definite etiology and the patient was rolled over on the uninvolved side, when the lung was seen to commence to inflate, the condition being watched under direct fluoroscopic vision. Complete recovery eventually took place.

Surgery.

541. Chronic Prostatitis.

W. S. PUGH (*Med. Journ. and Record*, January 19th, 1927, p. 105), discussing the surgical aspects of chronic prostatitis, regards the condition as a definite entity necessitating a complete cysto-urethroscopic examination to determine its extent, and only amenable to treatment by thorough removal of the polypoid masses found at the vesical neck and sometimes in the prostatic urethra. These masses are the foci of a chronic infectious process, and their complete removal can be effected by the fulgurating tip, electrotome, or prostatic punch. Prostatectomy is, he thinks, seldom indicated, and its performance in chronic prostatitis is usually contraindicated. Among the symptoms, in order of frequency, are itching and perineal pain, backache, lowered sexual power, testicular pain, premature ejaculations, and urethral fullness, together with such nervous symptoms as frontal headaches, neuralgias, joint pains, attacks of dizziness, and sexual neurasthenia.

542. Numerous Foreign Bodies in the Stomach.

A. GOLDSCHMIDT (*Zentralbl. f. Chir.*, February 19th, 1927, p. 465) reports the case of a man, aged 23, who was admitted to hospital complaining of very severe epigastric pain. He vomited black fluid and food, the faeces were "tarry," and the epigastric region was very tense and tender on pressure. A diagnosis of gastric ulcer was made. A skiagram showed that the fundus of the stomach was filled completely with a large mass of pins, nails, and coins. Gastrostomy was performed, and the operator removed 1,273 pins, 223 nails of various sizes, 15 French coins, 2 metres of small brass chain broken into short lengths, and four handfuls of small splinters of glass. The total weight of the collection amounted to 930 grams. A skiagram taken five weeks later showed four more nails lying between the abdominal wall and the vertebral column. A second laparotomy was performed, two nails were removed from the omentum, and another from the anterior edge of the liver. One nail had penetrated deeply into the liver, but as there were no signs of irritation it was not removed. The patient made an uninterrupted recovery. Subsequently he stated that three months before admission to hospital, in order to obtain his discharge from the Foreign Legion, he swallowed in two nights the various objects described above. Afterwards he deserted, and when admitted to hospital had said nothing as he feared arrest by the police. Goldschmidt cites a number of cases previously recorded in which foreign bodies were removed from the alimentary canal.

546. Infection of the Kidney.

J. R. ROBERTS (*Indian Med. Gaz.*, February, 1927, p. 75) discusses staphylococcal infection of the kidney with perinephritic abscess, and *B. coli* infection. The former has a direct relation to an attack of boils, and is an infarct of the cortical portion of a lobule or adjacent lobules, a small abscess forming under the capsule and burrowing into the perinephritic tissue. The symptoms are rigors and fever, with pain and a subsequent large swelling in the loin, but pus and blood are not necessarily found in the urine. Treatment is by incision and drainage. The forms of *B. coli* infection are the acute, subacute, and chronic. The acute is an intense infection of one kidney only with haemorrhagic infarcts, general congestion, and inflammatory oedema of the kidney substance. It is ushered in suddenly with rigors, the collapse is intense, and high fever, vomiting, intense pain in the loin, palpable kidney, and marked haematuria develop. Palliative treatment may suffice, but often immediate excision of the kidney is required. In the subacute form the apical portions of the lobules and the pelvis of one kidney, but not the cortex, are attacked, and the chief symptoms are nausea, vomiting, and haematuria. Treatment aims at the production of alkalinity of the urine as quickly as possible by large doses of potassium citrate (1 drachm every three or four hours). Hot fomentations to the loin must be assiduously applied, and the bowels evacuated. Rest in bed for three weeks is important. The subacute passes into the chronic form by recovery of the kidney; the infection remains, however, in the pelvis of the kidney, and vesical irritability sometimes occurs. Roberts maintains that the treatment of the chronic form by oral urinary antiseptics and by vaccines has conspicuously failed, and that the only effective treatment is lavage of the pelvis of the kidney through a ureteral catheter under anaesthesia. The antiseptic employed may be silver salts, flavine, boric acid, carbolates, or mercury salts, but the essential point is to use one which effects a cure in from four to six washings.

547. Surgical Treatment of Bilateral Pulmonary Tuberculosis.

E. RUAIS (*Thèse de Paris*, 1926, No. 250), who reports forty-five cases, maintains that in view of the frequency of bilateral lesions in pulmonary tuberculosis (about 25 per cent.) bilateral artificial pneumothorax is often necessary. The operation may be performed under the following conditions: (1) There may be a considerable interval between the operations on the two sides of the chest. (2) The pneumothorax on one side may be followed immediately by pneumothorax on the other. (3) Pneumothorax may be in existence on both sides at once, or partial bilateral pneumothorax may be performed in pregnancy as a prophylactic measure. The technique differs according to each of the varieties. In the first case the pneumothorax will be performed as if it were a primary operation. In the second case the first side treated may be decompressed or spontaneous absorption of the gas may be allowed to occur. In the third case a minimum degree of pressure should be exerted on one lung and a considerable degree on the other. The immediate results are said to be better than might be expected, as the operation causes a fall of the temperature and relief of the cough, and has a more gradual effect on the general condition and expectoration. In 70 per cent. of the cases favourable results were obtained. Bilateral artificial pneumothorax is contraindicated when the lesions have extended to the peritoneum, and still more when the pleura and mediastinum are affected. Early tuberculous laryngitis, far from being a contraindication, is an indication, as the larynx becomes contaminated by the sputum, and by preventing expectoration artificial pneumothorax has a curative effect. Ruais agrees that it is too early to assess the remote results, but bilateral artificial pneumothorax seems to him a very promising method in spite of the possible risk of perforation of the lung.

548. M. BORCHARDT, L. DÜNNER, and M. MECKLENBURG (*Med. Klinik*, January 28th, 1927, p. 123) suggest that, though artificial pneumothorax can seldom be induced on both sides, it is not only possible but advantageous to perform a phrenic avulsion on one side even when the other has been put out of action by a pneumothorax. They think that the therapeutic results of phrenic avulsion are greater than can be accounted for by its mere mechanical effect of paralysing the diaphragm, and they maintain that apical and adherent cases, though seemingly incapable of being influenced by such a measure, are improved by the operation. In view of this they suggest

that in a bilateral case pneumothorax should be induced on one side, and that at a later date, say in two weeks, phrenic avulsion may be performed on the other. Since such cases are of a grave nature, so large a percentage of arrests as in unilateral cases is not to be expected. The authors record eight cases, of which four were definitely improved.

549. Torsion of an Intra-abdominal Testis.

J. K. ORMOND (*Annals of Surgery*, February, 1927, p. 280) reports the case of a man, aged 42, who complained of sudden abdominal pain on the right side. The right testis was undescended, and a diagnosis of appendicitis or some lesion of an intra-abdominal testis was made. At operation a black swollen testis was found with one complete twist in its mesentery. This was removed and recovery was uneventful. Only five other recorded cases of a similar nature could be found in the literature. Incomplete descent with a developmental abnormality of the attachment of the cord to the testis seems to be the predisposing cause. In all the recorded cases except one the right side was affected, and faulty descent of the testis seems to occur more frequently on the right side. It is suggested that the presence of the caecum with its intermittent loading and pull on the peritoneum must have something to do with the frequency of torsion on the right side. Torsion seems to occur usually about puberty, though it is occasionally seen in infants.

Therapeutics.

550. Treatment of Scarlet Fever with Streptococcus Antitoxin.

J. E. GORDON (*Journ. Amer. Med. Assoc.*, February 5th, 1927, p. 382) records his observations on 317 cases of scarlet fever treated with serum at the Municipal Contagious Diseases Hospital, Chicago, and 367 controls. The serum used was a concentrated antitoxin prepared according to the Dick method. An intramuscular injection was given on admission, and in some severe cases repeated in twelve to twenty-four hours, but not more than three doses were given to any one patient. The general method of treatment of the two groups was the same, except that convalescent scarlet fever serum was used for a few of the more severe control cases. The definite drop in temperature described by Dick was not observed so frequently, but in many cases there was a decline from 104° or 105° to 99° within twenty-four hours. The immediate result was frequently a rise in temperature, probably as the result of the foreign protein injected. The total febrile period in days was shorter in patients receiving serum. The effect on the rash was usually striking. The typical rash faded in from eighteen to twenty-four hours. Desquamation began later in serum-treated cases than in controls, was usually slight, and lasted only a short time. There were fewer complications in the serum-treated cases, and haemolytic streptococci disappeared more rapidly from their nose and throat than in the case of controls.

551. Sodium Thiosulphate in the Treatment of Salvarsan Complications.

A. KRISTJANSEN (*Ugeskrift for Laeger*, February 24th, 1927, p. 154) reviews the various procedures recommended for the abortion or mitigation of the most serious complications of salvarsan treatment, and classifies these complications according as they occur (1) at the time of the injection, (2) a few seconds or minutes after it, or (3) days or weeks after it. The painful perivenous infiltrations, caused by the escape of some of the salvarsan into the tissues outside a vein, can be effectively treated by running from 10 to 15 c.cm. of sterile normal saline solution into these tissues through the salvarsan needle. The "nitroid crises" which occur a few seconds or minutes after an injection of salvarsan can be successfully combated by injections of 0.5 to 1 mg. of adrenaline once or twice a day. Much more difficult is the treatment of the late manifestations of salvarsan poisoning, but the author's experience with injections of sodium thiosulphate—first recommended for salvarsan poisoning in 1920 by Ravaut—is most encouraging. Ravaut argued that the reduction in the tissues effected by this drug would counteract the processes of oxidation for which he held salvarsan poisoning responsible. The author gave sodium thiosulphate by intravenous injection, the dosage for adults ranging from 0.6 to 1 gram per day, and the strength of the aqueous solution used being 10 per cent. The thirteen patients thus treated were classified in three groups, according as the drug was given (1) a week or less after the last salvarsan injection, (2) three to four weeks after the last salvarsan injection, or (3) in cases in which a preventive of salvarsan poisoning seemed necessary for infants suffering from congenital syphilis. Both in the treatment of severe salvarsan dermatitis and in the abortion of salvarsan poisoning in infants this drug proved most successful, only a few injections of sodium thiosulphate being required to arrest the development of salvarsan dermatitis in nine cases and to check its development in two cases of late salvarsan poisoning which threatened to be most dangerous and protracted. While this drug has never yet failed the author, he has also never observed any ill effects from it, and he recommends daily intravenous injections of from 0.6 gram to 2 grams in every case in which salvarsan poisoning threatens. It should also be given as a prophylactic to those patients who in the past have tolerated injections of salvarsan badly.

552. Vaccine Treatment and Prophylaxis of Whooping-cough.

O. PELLEGRINI (*La Pediatria*, January 1st, 1927, p. 71) reviews the literature and records his observations on 81 cases of whooping-cough at the out-patient department of the Alessandri Children's Hospital at Verona treated by stock vaccines. The ages of the patients ranged from 3 months to 6 years. The injections were given either subcutaneously or intramuscularly. No severe general reactions were observed; at most there was a slight rise of temperature (98.8° to 99.6°) and a local redness and infiltration at the site of injection. In severe cases slight haemorrhages from the bronchi and epistaxis were observed after the first few injections in patients who had not shown these symptoms previously. The results of treatment were as follows: 41 (51.3 per cent.) were cured, 23 (29.8 per cent.) were improved, 15 (19 per cent.) derived no benefit, and 2 died during the course of treatment. The results of prophylaxis were more successful, as out of 18 children who had been undoubtedly exposed to infection only 2 contracted the disease, and in a very mild form, which was completely cured after injection of 3 c.cm. of vaccine.

553. Treatment of Acute Early Syphilis.

S. S. GREENBAUM (*Therapeutic Gazette*, January 15th, 1927, p. 1) divides acute early syphilis into three stages: (1) the incubation period without cutaneous or serological manifestations; (2) chancre development without serum changes; and (3) the chancre with discoverable serum changes, and with or without the generalized exanthem of the clinical secondary stage. Treatment to abort the infection should commence not later than twenty-four hours after exposure. If a longer period than this has elapsed since risk of infection, unless a full series each of arsenobenzol and of bismuth is given it is much wiser to wait, since insufficient treatment in the early stages may only mask the disease. While awaiting developments serum tests should be made every third day for six weeks after the average incubation period has terminated. In the case of the person innocently and frequently exposed to infection by another with an unrecognized chancre a full series of injections of arsenobenzol and of bismuth should be given, but in no circumstances should one or two injections be administered, thus producing a false sense of security. For immediate abortive treatment the author advises local application of a 33 per cent. calomel ointment wherever possible, if exposure has occurred within three hours. In addition the injection of arsenobenzol (1.8 grams) or novarsenobenzol (2.7 grams) in divided doses, as often as the patient's tolerance permits, followed by 60 cg. of bismuth tartrate intramuscularly, in 200 mg. doses, will abort the disease. After either immediate or late abortive treatment the serum should be tested every three months for at least a year. Many records of reinfection have shown that efficient abortive treatment has cured syphilis. The consensus of modern opinion favours immediate treatment when a chancre appears, although the serum reaction may be negative. All genital erosions or ulcers should be examined ultra-microscopically, since the chances of cure are greatest when treatment starts while the serum is still negative. The intensive administration of large daily doses of arsenobenzols is dangerous, and acute poisoning may occur even after 150 mg. of novarsenobenzol; acute arsenical poisoning may not completely destroy the spirochaetes, as visceral, cutaneous, and neuro-syphilitic lesions have been known to occur subsequently. In the subintensive method the total dosage is less important than the quantity given at each injection. Large doses of the arsenobenzols are rapidly reached by increasing the earlier test doses, together with bismuth or mercurial injections, without any remissions. The first dose should be 150 mg. of the arsenobenzol given intravenously. In tolerant cases the dose at two, then four, five, and seven-day intervals should be rapidly increased to a full dose of 60 cg. of arsenobenzol or 90 cg. of novarsenobenzol to a total quantity of 4.8 grams of the former or 10.8 of the latter. This is larger than the quantity generally recommended, but the author considers it essential. This is followed at once by 2 to 3 grams of bismuth in 100 to 200 mg. doses; both courses should be repeated. This treatment lasts for about a year. Serum tests after the first arsenical course will be almost certainly

negative; they should be repeated at the end of the other series, then every three months for a year, after which comes a cerebro-spinal fluid examination and a provocative test. In sero-positive chancre, with or without secondary symptoms, the treatment is more prolonged and three courses of arsenobenzols should be given. Instead of the last bismuth course one of mercurial inunctions or injections is advised. The serum reactions should be persistently negative for two years before cure can be presumed.

Disease in Childhood.

555. Acute Intestinal Invagination in Small Children.

S. MONRAD (*Arch. Dis. in Childhood*, December, 1926, p. 323) records his experience of 115 cases of this condition; 34 patients were aged between 7 and 9 months, 73 were under 1 year, and no child was more than four years old. There were twice as many boys as girls. Almost all the cases fall into two large groups: (1) Large intestine invaginations, 75 per cent., including the ileo-caecal type comprising over 50 per cent. of the whole series, and the colic type. (2) Small intestine invaginations, 21 per cent. The treatment advocated is non-surgical reduction of the invagination, by traction and rectal irrigation, in children under 2 years of age with invagination of the colic, the ileo-caecal, or the iliac forms of, respectively, not more than thirty-six, twenty-four, or twelve hours' duration. All other patients should have immediate laparotomy, which, the author considers, would be the operation of choice in all cases if it were not for the heavy mortality associated with it. His technique is as follows. After emptying the bladder, and perhaps the stomach, the child is put under deep chloroform anaesthesia. If there is a large intestine invagination the surgeon first grasps its neck with both hands and compresses it for one or two minutes. He then steadies the neck with the left hand, takes hold of the apex with the right hand and tries to reduce the invagination by pulling the intussusception back through the intestine. In no case does he persist in these manipulations beyond ten or, at most, fifteen minutes. If it is an iliac invagination, where the head and the neck cannot readily be distinguished, he grasps the two ends of the tumour and cautiously pulls from each side alternately until the invagination is reduced. Such manipulation should not extend beyond five minutes. After the traction, whether successful or not, he injects water into the bowel, using, as Hirschsprung does, an enema syringe and Oser's sound, which are introduced as high up as possible. Only one or, at most, two such injections are given. The child is then put to bed with hot water bottles and an abdominal binder; if necessary injections of camphor and of salt solution are given. The author admits that it may be difficult in some cases to recognize whether the invagination has been reduced. If the treatment has been unsuccessful laparotomy is necessary. Particles of faecal matter returned with the enema afford satisfactory proof that the invagination has been reduced, but in nearly half the author's cases it was necessary to wait from two to twelve hours for a motion, while in four cases there was no motion passed for sixteen to thirty-four hours. The chief signs that indicate the failure of the treatment are: the return of the periodic attacks of colic, of the characteristic facial expression, and of the passing of typical blood and slime per anum. Severe symptoms of intoxication, such as vomiting, high temperature, and eclampsia, are said to occur in certain cases even though the invagination may have been successfully reduced. This intoxication resulted in death in 3 out of 75 successfully reduced cases in the author's series. Over the whole of his cases he has had a mortality of 19 per cent., with traction alone 14 per cent., and with traction and secondary laparotomy 60 per cent., figures which, he maintains, compare favourably with the results of the primary operation.

555. Mastoid Infection in Infants.

A. M. ALDEN (*Arch. of Oto-Laryngol.*, January, 1927, p. 39) recalls that the tympanic cavity and ossicles of a child are practically the same size and shape as those of an adult. The Eustachian tube is much shorter and wider and the upper part of the tympanum is filled with mesodermal folds which tend to block the aditus. The wide Eustachian tube accounts for the fact that it is possible to have a middle ear full of pus, which discharges through the tube into the nasopharynx and leaves the tympanic membrane of almost normal appearance. Incision in such cases reveals the presence of pus. In the first of the two types of mastoiditis in infants there is a general constitutional disturbance with pyrexia, irritability, and pain for a day or two. A swelling appears behind the ear, signifying perforation of the cortex and reduction of the pressure; this is accompanied by considerable relief and amelioration of the symptoms. Incision and cleansing of the mastoid cells is almost always followed by a rapid and complete cure. The causative organism is usually a staphylococcus. The second type is due to a haemolytic streptococcus and does not give rise to external signs. The extension of the infection is along the blood vessels of the bone, and there are very considerable constitutional symptoms, particularly gastro-intestinal. The diarrhoea is so severe as to warrant the term "cholera infantum." The children are very ill and have been treated entirely for the gastro-intestinal disturbance until they have died of emaciation or of some complication of the otitis media. The only signs of change in the drum may be slight alteration in the colour and sagging of the superior wall of the meatus. The mastoid process and the general condition require very vigorous treatment.

556. Relapsing Fever in Childhood.

G. S. LEVY (*Zeit. f. Kinderheilk.*, December 23rd, 1926, p. 627) records his observations on 360 cases of relapsing fever in children up to the age of 16 observed at the Odessa Paediatric Clinic from 1917 to 1924, with the histories of seven cases illustrating the association of relapsing fever with typhus. His conclusions are as follows: (1) Rise of temperature after a short apyrexial period of three or four days should suggest that relapsing fever is complicated by another disease, for normally the duration of the first apyrexial period is not less than a week. (2) When relapsing fever is complicated by typhus the skin eruption is usually absent. (3) Cases where relapsing fever was complicated by typhus ran their course without any further complication. (4) Leucocytosis before the crisis usually indicates a fresh attack. A normal number of leucocytes or their diminution contraindicates the appearance of a fresh attack. (5) Insufficient nourishment on the part of the mother is a cause of frequent attacks of relapsing fever in the breast-fed infant. (6) The change in immunity due to hunger may cause an increase in the number of attacks and an atypical character of the apyrexial interval.

557. Idiopathic Osteo-Psathyrosis.

IN an account of this form of bony friability M. MIRAGLIA (*La Pediatria, November 15th, 1926, p. 1228*) distinguishes between this disease and other causes of fragilitas ossium. He considers the reported cases of osteogenesis imperfecta, which, he contends, fall into two groups: (1) the osteogenesis imperfecta of Vrolich, in which there is defective ossification, as shown by the delayed and poor reparative processes in the fractured bones (absence of callus), and the associated aplasia of the cranial bones and sclerotics (blue); (2) the osteo-psathyrosis of Lobstein, in which the cranial bones and sclerotics are unaffected, the bones are normal at birth, the time of appearance of the fractures is far later, and there is prompt and abundant callus formation. When the disease makes its first appearance the diaphyses of the long bones become subject to an increased activity on the part of the osteoclasts, leading to absorption of the inner layers of the compact bone with consequent enlargement of the marrow cavity, showing a typical picture by *x* rays. Miraglia describes the case of a girl, aged 15 months, in which the family history was entirely negative although both parents gave positive Wassermann reactions, as did the patient. At the age of 6 months a trivial accident caused the first fracture, and subsequent fractures occurred after slight injuries. The child showed no signs of rickets; the anterior fontanelle was almost closed and the cranial bones were normal. The diaphyses of the long bones were abnormally slender, causing the epiphyses to appear enlarged. There was no deformity of the bones unaffected by fracture; this and the normal body calcium exchange excluded osteomalacia. *Radiograms* showed the typical reduction of compact bone, increase in size of the marrow cavity, and plentiful callus associated with the fractures. There was sympathicotonia, though at this age vagotonia is normal. Discussing the pathogenesis of this disease, Miraglia points out that infancy and old age are the two periods of most energetic physiological absorption of bone, accompanied in infancy by rapid formation of new bone by the periosteum, which quickly replaces the skeletal tissues of foetal life. There is an equilibrium between destruction and deposition which is disturbed in osteo-psathyrosis in the direction of increased absorption, which should tend to become less with age, as is indeed the case. Several authors have described an actual increase in the number and activity of the osteoclasts, and Miraglia holds that all the data go to prove that it is these and not the osteoblasts or bone-forming elements which are at fault; the reverse of this is probable in osteogenesis imperfecta. He thinks that syphilis in this case only acted indirectly, probably causing dysfunction of the thyroid and parathyroid glands, the sympathicotonia, and resultant effect on the bones. There was no direct syphilitic affection of the skeleton, and he contrasts the rarity of this disease with the frequent occurrence of congenital syphilis.

Treatment was antiluetic and by ultra-violet rays, the beneficial effect of which Miraglia attributes to their acting on the endocrine system, in this case preventing further fractures and restoring the radiographic appearances to normal.

Obstetrics and Gynaecology.

558. Induction of Labour by Castor Oil, Quinine, and Pituitary Extract.

A. MATHIEU (*Amer. Journ. Obstet. and Gynecol.*, February, 1927, p. 223) considers that the value of castor oil, quinine, and pituitary extract in the induction of labour is not sufficiently recognized as being the one safe method in combating many abnormalities. Two ounces of castor oil and 10 grains of quinine sulphate are given, and followed exactly two hours later by a hot simple enema. When this is about to be expelled 3 minims of pituitary extract are injected hypodermically, and this dose is repeated every half-hour until labour starts, after which the labour is conducted as if its onset had been normal. Failure is admitted and the procedure stopped at the end of eight hours if no sign of labour is present; a sedative is given and the process is repeated after an interval of twenty-four or forty-eight hours. In a series of 91 cases there were only three failures, induction being successful in the remaining patients without any maternal or foetal deaths; 62 inductions were successful on the first attempt, 20 on the second, and 6 on the third. In 33 the labour terminated normally, 51 required low or mid forceps delivery, version and breech extraction occurred in 5, and Caesarean section was needed in 2. The method was successful in all the 39 multiparae, the average number of pituitary extract injections needed being six and a half; in the 52 primiparae the average number in the successful cases was six, in the 3 failures ten and a half, and in only 8 cases were more than twelve injections given on account of urgency. Mathieu states that the method is free from the dangers and difficulties attending the use of the bag or bougie, and he urges its adoption in those cases in which induction before term is indicated.

559. Etiology of Eclampsia.

E. CARLONI and M. FERRARI (*Ann. di Ostet. e Ginecol.*, January, 1927, p. 1) have analysed the records of 134 cases of eclampsia treated in Bologna between 1901 and 1925. They find it to be three times more common in primiparae than in multiparae. In both the incidence is highest during the age periods 15 to 20 and 35 to 45; for example, 9.3 per cent. of primiparae aged 15 to 20 were eclamptic, as contrasted with fewer than 3 per cent. of those aged 20 to 35. Comparing the incidence of eclampsia with the menstrual history of various patients the authors find that of patients with normal menstruation about 1 per cent. suffer from eclampsia; of those with genital hypofunction (Stameni), shown by scanty menstruation, late puberty, and early menopause, about 1.5 per cent.; and of those with hyperfunction, indicated by such signs as profuse menstruation, about 0.4 per cent. The incidence of eclampsia appears to be considerably greater among those who during the early months of pregnancy have shown well marked functional disturbances—in primiparae six times as great; moreover, among those who have not had troublesome functional symptoms in early pregnancy the onset of eclampsia is apt to be sudden, without prodromal pre-eclamptic danger signals. About one-fifth of the present series were cases of post-partum eclampsia, of which the onset was usually abrupt and the course benign. There were no cases of eclampsia before labour.

560. The Toxaemias of Pregnancy.

J. W. WILLIAMS (*Journ. Amer. Med. Assoc.*, February 12th, 1927, p. 449) classifies the toxaemias of pregnancy as eclampsia, pre-eclampsia, chronic nephritis, eclampsia superimposed on chronic nephritis, and low kidney reserve. He notes that in eclampsia when recovery ensues the return to health is very prompt, and the disease is unlikely to recur in subsequent pregnancies; after chronic nephritis recovery is tardy, and exacerbations occur earlier with each successive pregnancy. In pre-eclampsia the patient is acutely ill and presents a very high blood pressure and urinary albumin content, amaurosis, epigastric pain, and the typical blood chemistry picture of eclampsia. In these cases convulsions can be prevented only by the most prompt termination of pregnancy consistent with safety. Cases of low kidney reserve may be due to congenital causes, or to such factors as may have lessened the number of functioning glomeruli without producing chronic nephritis. There is no change in the chemical constitution of the blood. Oedema, headache, and more or less malaise are present, but the condition usually improves with rest in bed and a restricted diet. In eclampsia superimposed on chronic nephritis patients are more ill than with uncomplicated eclampsia, the blood pressure is usually high, and the amount of albumin excessive. Chemical examination reveals marked retention of non-protein nitrogen, and after recovery the symptoms of renal insufficiency persist. Williams believes that the ultimate cause of eclampsia and other late toxaemias of pregnancy is the formation of some chemical substance which leads to a profound disturbance of metabolism, accompanied by certain organic lesions, but whether its origin is in the mother, child, or placenta is unknown. He adds that until this problem is solved the treatment of eclampsia must remain empiric, the most effective measure being prevention by close pre-natal care. In both pre-eclampsia and nephritic toxaemia pregnancy should be terminated as soon as the condition becomes serious. Williams advocates a modified Strogonoff routine in mild as well as severe cases of eclampsia. He states that all the generally used anaesthetics superimpose an additional toxaemia on that of the disease, and that operative treatment will not show better results until some non-toxic anaesthetic is discovered. He thinks that Caesarean section performed under the usual general anaesthetics is the worst treatment for eclampsia.

561. Transmission of Tuberculosis from Mother to Foetus.

M. A. COUVELAIRE (*La Gynécologie*, December, 1926, p. 725) reports a further series of 126 cases of parturition in women suffering from pulmonary tuberculosis. He finds that in mothers who have slowly advancing disease, with slight or transitory aggravations during gestation, the infection exercises little or no influence on the intrauterine development of the foetus. Of 41 pregnant subjects, however, with rapidly advancing disease, 13 gave issue to stillborn foetuses or children dying shortly after delivery. Examining in conjunction with Calmette, Waltis, and Lacomme six such foetuses, with a view to detection of tuberculous infection, he found that (1) in three cases tubercle bacilli could be found by direct examination of foetal lymphatic glands which anatomically did not appear to be tuberculous; (2) ganglionic tuberculosis was present in a certain number of guinea-pigs inoculated with fluid from extracts of coronary or mesenteric glands or fragments of liver or spleen—this was true for all foetuses; (3) in two instances inoculation of guinea-pigs with filtrates from mesenteric glands or those of the hilum of the liver was followed by detection of Koch's bacillus in certain of the animals' lymph glands—without tubercle formation. Studying children who survived the puerperal period but died with the syndrome of "progressive denutrition," Couvelaire and his fellow workers found that in guinea-pigs inoculated with ground-up lymph glands, or with filtrate from lymph glands or mixed viscera, the lymph glands—in the absence of anatomical tuberculous lesions—contained acid-fast bacilli. It is concluded that apart from very exceptional transplacental transmission of tuberculous virus with lesions developed *in utero* there is also transplacental passage of a tuberculous virus which does not produce a specific anatomical lesion. These investigations are regarded as pointing to the existence of a tuberculous ultra-virus capable of passing through the placenta in the same way as it traverses a filter; of such a virus Koch's bacillus would constitute a more resistant form.

562. Treatment of Carcinoma of the Female Genitalia.

I. IKEDA (*Zentralbl. f. Gynäk.*, February 12th, 1927, p. 407) reports 461 cases of carcinoma of the female genitalia treated by radium between 1915 and 1923; of these, 432 were cervical; 198 are still living, the deaths including those from all causes up till the end of 1925. He shows that the number living from the end of the second and third years after treatment is remarkably constant; local recurrences and metastases occur most often from the end of the first to the end of the second year and then decrease in number. Among conditions complicating the carcinoma he mentions four cases of myoma which were much benefited by the treatment, and seven of pregnancy, of which two women in the second and third months aborted during treatment and died later. The other five women were in the latter half of pregnancy; all went to full time and had healthy children. Three of them became pregnant again and all died of haemorrhage, having given birth to living children, the cause of death being the scar tissue formed in the passages; for this reason Caesarean section is advised in such cases. Damage to neighbouring organs, specially the rectum and bladder, is usually the result of overdosage. Ikeda's youngest patient was 23 years of age, and in 45 per cent. of his cases malignancy started between the ages of 41 and 45. Recurrence and metastasis were more frequent in the patients under 35 to 40 and their prognosis was worse. Women in good circumstances come earlier for treatment

and consequently do better. All the 432 patients were married, 14 per cent. were sterile and 86 per cent. had from two to twelve children; the maximum number of cases was found in women with four children. As regards heredity 376 had no such history; 56 had familial, 15 paternal, and 28 maternal histories of malignant disease. Of 18 patients with carcinoma of the body of the uterus, 61 per cent. are living, and of 9 in whom the vagina was the seat of disease 33 per cent. In two cases affecting the external genitals a radical operation was performed first; in one the carcinoma recurred and she died; the other patient is alive.

Pathology.

563. The Effect of Aeration on the Bacteriophage.

F. D'HERELLE (*C. R. Soc. de Biologie*, February 25th, 1927, p. 451) has investigated the effect of aeration on the activity of the bacteriophage. He used four strains, active respectively against *B. dysentariae*, a staphylococcus, *B. pestis*, and *V. cholerae*. The bacterial suspensions were standardized to a strength of 250 million per cubic centimetre. Tests were made with 10 c.cm. of bacterial suspension at a temperature of 37° C., and the time taken for complete lysis to occur was noted. Under ordinary conditions the dysentery bacillus was lysed in five hours, the staphylococcus in twenty-four hours, the plague and the cholera bacilli in thirty-two to forty hours. In the dysenteric and staphylococcal suspensions secondary growth occurred after three to six days; in the plague and cholera suspensions the dissolution was never complete, and secondary growth became apparent a few hours after the minimal opacity had been reached. Under conditions of strict anaerobiosis lysis occurred very much more slowly than when the tubes were merely plugged with wool and exposed to the air. The staphylococcal suspension, for example, was not cleared for four days, and secondary growth did not become apparent for at least twelve days. When, however, the tube suspensions were exposed to a current of air in a thin layer, so as to obtain the maximum aeration, lysis occurred with great rapidity. The dysentery suspension was cleared completely in two and a half hours, and the other three suspensions in seven to eight hours. After ten passages under these hyperaerobic conditions the activity of the bacteriophage had so increased as to cause lysis of the staphylococcal, plague, and cholera suspensions in four hours; secondary growth often did not occur for two or three days, sometimes not at all. The author considers that these observations will be of value in the preparation of bacteriophage for therapeutic uses.

564. Benign Glycosuria.

K. FABER (*Journ. Clin. Invest.*, December 20th, 1926, p. 203) emphasizes the importance of distinguishing between the two essentially different forms of glycosuria—namely, that due to a disease of the islands of Langerhans, and the variety traceable to a deficient blood sugar regulation, which is dependent either on a persistent abnormally low threshold or on an habitually high alimentary blood sugar rise, or on both. In these cases the glycosuria is the result of a constitutional abnormality rather than of disease, and is harmless to the individual. Faber maintains that the correct diagnosis will depend upon the fasting blood sugar. If this is abnormally high a diagnosis of true diabetes should be made. If normal, the examination should be repeated several times at intervals of a few weeks, the patient being allowed a carbohydrate diet. Should a normal fasting blood sugar continue in these circumstances, the glycosuria is most probably of benign origin. If a low threshold is the only cause of the condition the case must certainly be considered as harmless. He adds that he has not heard of any definitely established case of benign glycosuria becoming changed into true diabetes.

565. The Acetic Anhydride Test of Cerebro-spinal Fluid.

J. G. [illegible] E. A. CARMICHAEL (*Journ. Neurol. and* [illegible], 1927, p. 220) have investigated the value [illegible]ride test of the cerebro-spinal fluid in a series of cases of general paralysis and other forms of neuro-syphilis. The cerebro-spinal fluid tested was never over forty-eight hours old, and was not heated. The authors remark that when the test cannot be performed at once the fluids should be kept in an ice chest; they may be stored thus for a week or more without affecting the results. In the test 1 c.cm. of the fluid is measured into a test tube and 0.3 c.cm. of chemically pure acetic anhydride added. The tube is gently agitated so as to form an emulsion, and then, drop by drop, 0.8 c.cm. of chemically pure sulphuric acid is added. If there is no immediate colour change the tube is again shaken gently. This coloration usually occurs when 0.6 c.cm. of the acid has been added, the additional 0.2 c.cm. merely intensifying it. The reaction is rapid and fleeting, and requires immediate recording. A positive result is shown by the appearance of a very definite lilac tint of varying shades. Other colours were considered negative, and it was found that a dirty brown hue was associated with a high protein content. The authors report that the reaction cannot be associated with any single one of the usual syphilitic reactions or combinations of these. They assume that the causal factor must be some other substance in the fluid than that producing the other serological reactions, and suggest that it may be due to an increased cholesterol content. They obtained a positive result in 15 out of 16 cases of dementia paralytica. They add that a positive reaction may occur in secondary neuro-syphilis, and that cases of cerebral degeneration may give a weak reaction. No definitely positive result was obtained in any case of tabes dorsalis.

566. Tubercle Bacilli in the Faeces.

P. CORSONELLO (*Bruxelles Méd.*, January 23rd, 1927, p. 373) states that all tuberculous patients do not expectorate, and that in granulia and diseases of the rhino-pharynx it is useless to search for the tubercle bacillus. The presence of this micro-organism in the faeces in granulia and articular tuberculosis has been reported by numerous workers, and Corsonello affirms that Koch's bacillus is constantly present in the faeces of the majority of pulmonary tuberculous cases. He considers that faecal examination is a certain diagnostic method and allows early bacteriological confirmation of the disease in latent cases or in those with no expectoration, that the bacillus is not met with in the faeces of healthy individuals, and that its presence in those of tuberculous patients establishes a possible source of infection. Corsonello follows the technique of Moreau and Venot, and, agreeing with Calmette that the bacilli reach the intestinal tract from the lungs by way of the biliary passages, he administers some days before the examination a cholagogue, such as calomel. A faecal fragment is triturated with a 25 per cent. sodium chloride solution till semi-liquid, and then filtered through gauze. To the filtrate equal parts of ether and ligroine are added and the mixture centrifuged. Films of the deposit are made, and stained by the Ziehl-Neelsen method. The author adds that the films should be very carefully examined as the number of bacilli present is small. A single negative search is valueless, and many films, taken at regular intervals, should be studied.

567. Experimental Epidemiology of Tuberculosis.

D. PERLA (*Journ. Exper. Med.*, February 1st, 1927, p. 209), having observed a number of spontaneous infections in animals kept in the same room with tuberculous animals, tried to determine more precisely the frequency with which spontaneous transmission of the disease occurs. The general plan of the experiments was to place artificially infected guinea-pigs in the same cage with normal guinea-pigs and to observe the animals for some months. In order to maintain the conditions as constant as possible every infected animal that died was replaced by a fresh infected animal, and every normal animal that died by a fresh normal animal. The proportion of infected to normal guinea-pigs varied from cage to cage. In the first experiment the guinea-pigs were infected by intraperitoneal inoculation of a small dose of a virulent human culture. In one cage there were 3 infected and 9 normal animals; in another 6 infected and 6 normal; and in a third 9 infected and 3 normal. Observation was maintained for seven and a half months. Of 13 normal animals that survived the entire period 3 acquired tuberculosis. In the second experiment the guinea-pigs were infected by subcutaneous inoculation, so as to provoke abscess formation and ulceration. Of 8 normal guinea-pigs exposed in the same cages to the animals with open lesions for seven months 3 developed tuberculosis. In the third experiment larger numbers of animals were placed in the same cage, so as to test the influence of overcrowding. Infection was performed by the intraperitoneal route. In one cage where the infected and normal animals were present in equal numbers—6 and 6—no spontaneous infections occurred. In another cage—6 infected and 12 normals—29 per cent. of the normal animals developed tuberculosis. In another cage—6 infected and 18 normals—60 per cent. of the normal animals developed tuberculosis. And in the last cage—6 infected and 24 normals—36 per cent. of the normal animals developed tuberculosis. In all the experiments the infection appeared to occur by the alimentary tract, the chief lesions being in the cervical and mesenteric lymph glands. It was shown that the animals injected intraperitoneally excreted tubercle bacilli in their faeces, especially for a week or two before death. On the whole the greater the intensity and duration of exposure to infection, the higher was the incidence of spontaneous tuberculosis in the normal animals.

EPITOME OF CURRENT MEDICAL LITERATURE.

Medicine.

568. Intraventricular Haemorrhage.

I. J. SANDS and M. LEDERER (*Journ. Nerv. and Ment. Dis.*, April, 1927, p. 360) record three cases of intraventricular haemorrhage and summarize the literature on this subject. Sanders stated that the most common and direct cause of primary intraventricular haemorrhage was rupture of some vessel on or near the ventricular walls, and mentioned seven possible sources of the blood. According to Gowers, the haemorrhage usually comes from the vessels of the choroid plexus. Tilney and Casamajor described a case which was under their close and continuous observation; they divided the symptoms into those resulting from haemorrhage into the cisterns, and those due to the extent of the haemorrhage into the ventricles. Death from intraventricular haemorrhage is usually inevitable, but the rare possibility of recovery is shown by a case reported by Launin. In the three cases reported by the present authors the symptoms were in close agreement with those described by Tilney and Casamajor. In one case it was found at the necropsy that the haemorrhage filled the entire ventricular system; the basilar and both middle cerebral arteries showed atheromatous areas, but the bleeding point could not be found. In another case a subarachnoid haemorrhage filled the cerebro-medullary cistern; numerous cerebral arteries were markedly sclerosed, and a sagittal section revealed a large pontine haemorrhage filling the fourth ventricle. In the third case the entire ventricular system was filled with blood clot, and two aneurysms on the left posterior communicating artery had ruptured, one into the left inferior horn of the lateral ventricle, the other into the subarachnoid space. The authors state that the onset of intraventricular haemorrhage is always sudden, and that if any premonitory symptoms seem to be present, they are due to some concomitant malady. They add that the acute onset of cranial symptoms in a man of known cerebral arteriosclerosis or of suspected intracranial aneurysm, with the early appearance of coma, persistently haemorrhagic spinal fluid, and spasms of the entire somatic musculature with absence of signs of paralysis, should lead to a diagnosis of intracranial haemorrhage.

569. Heredity in Simple Goitre.

W. R. BRAIN (*Quart. Journ. Med.*, April, 1927, p. 303) reports a series of six families including twenty-six persons suffering from simple goitre; in two of these families cases of goitre occurred in four successive generations. In a second series of five families there were twelve cases of simple goitre associated with congenital deaf-mutism. Brain submits evidence that the environment alone cannot account for the development of goitre and suggests that hereditary predisposition is an important factor in its etiology. A maternal goitre may activate a latent tendency in the child. He discusses the relation between such a tendency and the environment, with special reference to the iodine content of the soil and water, reconciling this etiology with McCarrison's emphasis on an infective process. Goitre seems to be transmitted more frequently by women than by men, the former being apparently more susceptible to iodine deficiency. Brain suggests that the difference between the two sexes as regards transmission is not generic, the predisposition being transmitted equally by both sexes, though it appears more frequently in the children of affected women owing to the influence on the foetus of the established disturbance of thyroid function in the mother. *He concludes that simple goitre may be the manifestation of more than one abnormal hereditary factor, there being a Mendelian dominant, affecting women particularly, which is latent in the absence of iodine deficiency, and also a Mendelian recessive, manifested equally by males and females, and occurring in the presence of a normal iodine supply.*

570. Mediastinal Pleurisy and Bronchiectasis.

E. RIST, P. JACOB, and P. TROCMÉ (*Ann. de méd.*, February, 1927, p. 144), who record seven illustrative cases in patients aged from 16 to 53, state that mediastinal pleurisy, of which the morbid anatomy was first described by Laennec and later by Andral and Cruveilhier, was not recognized as a clinical entity until the end of the nineteenth century. Attention was first paid to the acute purulent forms, such as the posterior mediastinal empyema described by Dieulafoy, characterized by dysphagia, recession, paroxysmal cough, and the formation of a collateral circulation. Subsequently attention was drawn to anterior mediastinal empyema and the difficulty in distinguishing it from acute pericarditis, as well as to anterior serous mediastinal pleurisy. The advent of x rays enabled an earlier and more certain diagnosis of these conditions to be made. Chauffard in 1902 showed that a paravertebral vertical shadow was characteristic of posterior mediastinal serous pleurisy. The present authors have found that dilatation of the bronchi is the condition most frequently associated with the radiological appearance of posterior mediastinal pleurisy. They maintain that every patient in whom a triangular shadow suggesting mediastinal pleurisy is found should be given an intratracheal injection of lipiodol. If the presence of bronchiectasis in the neighbourhood of the pleurisy is indicated it will have to be decided whether this is suppurative or, as is the rule, adhesive, and the treatment will then have to be directed accordingly.

571. Clinical Manifestations of Enlarged Thymus.

E. A. MORGAN, H. A. ROLPH, and A. BROWN (*Journ. Amer. Med. Assoc.*, March 5th, 1927, p. 703) have investigated 54 cases of enlargement of the thymus gland, 28 in males and 26 in females. In all except 2 cases the enlargement was accompanied by suggestive manifestations, which the authors have tabulated in the order of relative frequency. Spasms of holding the breath were observed in 29 cases, syncope in 9, cyanosis in 8, a continual hoarse cough in 7, noisy nasal breathing in 6, and choking attacks in 5. The authors think that these symptoms are not toxic, but that they are caused mechanically by vagus stimulation; in 96 per cent. of the cases x-ray treatment brought rapid relief. Recurrence of thymic enlargement or of clinical manifestations was recorded in 12 cases, but repetition of the x-ray treatment resulted in complete recovery in each case.

Surgery.

572. Cancer of the Breast simulating Erysipelas or Mastitis.

H. NÖLLE (*Zentralbl. f. Chir.*, March 19th, 1927, p. 724) describes six cases of mammary cancer in young women in which the early symptoms simulated erysipelas or mastitis. One patient lived for fifteen months after she first observed an irritation of the left nipple; this was followed by swelling of the breast and reddening and oedema of the skin, originating in the outer lower quadrant. The temperature was normal and there was no lymphadenitis. An exploratory incision confirmed the diagnosis of Paget's carcinoma. The skin condition precluded a radical operation, but autohaemotherapy, and simultaneously intensive x-ray treatment, arrested the morbid process for a long time. A severe rigor with temperature of 104° F. preceded an invasion of the right breast, and the skin became bright red suddenly, the erythema being sharply defined and the skin slightly tender. No direct connexion with the carcinoma of the left breast was found. The condition suggested erysipelas originating in the eczematous condition of the nipple; it subsided under alcohol dressings, but at the site of the redness a vesicular scleroderma appeared, followed by rapid development of nodules and the characteristic appearance of cancer *en cuirasse*, with slight local superficial ulceration. Later there was a milder recurrence of fever and erythema, and, towards the end, metastatic nodules appeared. The rapid extension of carcinoma *in a form resembling erysipelas* is very unusual, but Nölle refers to several recorded cases in which this condition was associated with Paget's disease of the nipple. Another woman, aged 27, discovered a swelling as large as a plum in the left breast three weeks after childbirth. The breast increased rapidly in size and became red with a stony hardness; the axillary glands were swollen. The milk was drawn from the other breast and a severe inflammatory swelling was found. No improvement followed three weeks' treatment, and an exploratory incision showed carcinoma of the skin. A woman, aged 21, complained of pain in the right breast, and redness of the skin suggested abscess formation, though no pus was found on excision. Klose found that the breast was of stony hardness; in the lower inner quadrant there was a tumour as large as an apple. The skin was red, with a sharply defined raised margin resembling that of erysipelas. There were no nodules. An exploratory incision showed that it was a case of medullary carcinoma, and the patient died within three months. In two of Klose's cases

irregular atypical fever persisted. Another patient with what appeared to be a left mammary abscess of four weeks' duration was found to have a hard, slightly tender tumour as large as a fist in the outer lower quadrant of the left breast. There was no fever, but the skin over the tumour was red and oedematous, and there was slight deep fluctuation. Above the tumour was a second one as large as a walnut. There were no skin changes, but the axillary glands were slightly swollen. An exploratory puncture showed a cavity containing necrotic tissue and serous fluid, and ablation of the breast and the subjacent muscles was performed, the axilla being cleared. The patient improved at first, but died from exhaustion on the ninth day. The autopsy revealed generalized metastases in the lungs, liver, spleen, kidneys, ovaries, and peritoneum. The sections showed large-celled carcinoma with some cirrhotic portions. The peculiarity of all these cases was the surprising resemblance of very malignant mammary cancer to erysipelas or inflammatory swellings. In nearly every case the original diagnosis was erroneous.

573. Arthritis following Typhoid Osteitis.

MOURGUE-MOLINES (*Bull. Soc. Sci. Méd.*, March, 1927, p. 130) reports the case of a patient with arthritis of the knee who had suffered from a severe attack of typhoid fever thirteen years previously. Following the attack fistulas and areas of osteitis persisted in various bones of the body, *B. typhosus* being isolated from the pus. Curetting was followed by apparent cure after some months. The patient was able to resume work, but thirteen years later, owing to a slight injury, arthritis of the right knee developed. Two symmetrical fistulas at both condyles of the femur were discovered, and bacteriological examination again revealed the presence of *B. typhosus*. Arthrotomy, with drainage, was performed, and an autogenous vaccine administered. No benefit being obtained, a stock vaccine was tried, with slightly better results; the Wassermann blood test was strongly positive, and a course of novarsenobenzol was begun. Despite all treatment no cure followed, and a perisynovitis, one of the signs of tertiary syphilis, still persists. The author draws attention to the following points in this case; the long period of latency of *B. typhosus* and its site of election, this micro-organism rarely attacking articulations: the association of this bacillus with the *Spirochaeta pallida* evidently causing a persistency of the lesions; and the improvement following the use of a stock rather than an autogenous vaccine.

574. Duodeno-Jejunal Diverticula and Intestinal Obstruction.

A. KROGIUS (*Deut. Zeit. f. Chir.*, March, 1927, p. 273) has collected eleven cases, including one of his own, in which diverticula of the duodenum, jejunum, or ileum have given rise to symptoms of acute intestinal obstruction. Seven of the patients were males and four females. The youngest was aged 6 years, one was 20, and another 27, while all the rest were over 40. In one case the disease appeared in the form of acute peritonitis due to gangrene of a duodenal diverticulum. In all the rest the clinical picture was that of mechanical intestinal obstruction, which developed slowly in four cases and rapidly in six. In four cases the diverticula were situated in the duodenum (in two of these diverticula were also present in the upper part of the jejunum), in one in the duodeno-jejunal flexure, in four in the jejunum, and in one in the ileum. In four cases there was only one diverticulum, in two there were two, and in five from five to sixteen. In only one case was the diagnosis of diverticulum made before operation by means of an *x*-ray examination. One patient was believed to have acute appendicitis, and in all the rest the diagnosis of intestinal obstruction was made without its nature being determined. Laparotomy was performed in ten cases and six recovered, including Krogius's patient, a previously healthy woman, aged 64, who suddenly developed symptoms of high intestinal obstruction, which was found to be due to a diverticulum at the duodeno-jejunal junction.

575. Retroperitoneal Adenosarcoma simulating Appendicitis.

S. LINDQVIST (*Zentralbl. f. Chir.*, March 12th, 1927, p. 662), operating on a boy, aged 3, for what appeared to be appendicitis, found a large tumour, the upper pole of which pushed the diaphragm upwards and outwards and was adherent to the under surface of the liver, while its lower end was attached to the upper pole of the right kidney. The medial surface of the tumour sloped deeply inwards and was also extensively adherent to the under surface of the liver and to the stomach. To remove the tumour it was necessary to open the peritoneum. Rather free bleeding from the liver and stomach was arrested by catgut sutures, and there was no appreciable injury to the stomach wall. The right kidney was removed. No metastases were found. The great portion of the cavity was closed and some small rubb drainage tubes were inserted. Although the operation last only thirty minutes under light ether anaesthesia, the patie was very collapsed, but quickly improved after intraveno injection of normal salt solution, and in the evening was o of danger. The tumour, which weighed 2½ lb., was found be an embryonic mixed tumour (adenosarcoma); there w no evidence of any connexion with the suprarenal capsul In some parts it resembled a pure leiomyoma or lei myosarcoma, in others there was distinctly differentiat epithelial tissue suggestive of an adenocarcinoma, wi occasional retention cysts. Lindqvist considers that t sudden onset of severe pain and local muscle rigidity justifi a diagnosis of acute appendicitis, but he regrets that differential blood count was made before the operation.

Therapeutics.

576. Cardiac Medication.

ACCORDING to V. GALLEMAERTS (*Bruxelles Méd.*, March 27t 1927, p. 699) the therapeutic effect of digitalis is the resultar of a series of actions on the various properties of cardia muscle re-establishing the functional equilibrium of th myocardium. The four functions of cardiac muscle ar automatism, conductivity, excitability, and contractility and digitalis acts on these different functions, its actio varying with the strength of the dose given. A weak dos has no effect on automatism, a medium dose diminishes i and a strong dose augments it until fibrillation occurs. Co ductivity is not affected by a small dose, but is diminishe by a larger one, and signs of heart-block occur. The actio of digitalis on contractility is more complex, but, generall speaking, a weak dose lessens while a medium dose increase it. Excitability is increased by both weak and moderate doses but owing to the effect of digitalis on the other functions, an especially by reason of the improvement of the coronar circulation, excitability is diminished indirectly. It has bee shown that there are three phases in the action of digitalis (1) Systole and diastole are prolonged and the cardiac actio is retarded by diminution of automatism. (2) Systole is stil more prolonged and strengthened, the quantity of circulatin blood being increased. (3) In the third or toxic phase cardia action becomes rapid and irregular, the quantity of circu lating blood diminishes, and the intraventricular pressur falls. The author thinks it is best to give a moderate dos (about 1 mg. of digitaline) two or three times and then t stop it; this form is more reliable than the official prepara tions. He prefers to give it in aqueous solutions. *Digitalis* often fails in cases of cardiac dilatation with a slow, regular pulse; in these cases renal diuretics, such as theobromine, diuretine, and squills, are indicated. Instead of *digitalis*, strophanthus and ouabain should be prescribed; the latter increases the tonicity of the myocardium and is thus particularly useful in severe dilatation, acting more *rapidly* than digitaline. Gallemaerts insists that radiography and electro-cardiography are most important adjuncts in the treatment of cardiac dilatation, and states that disastrous results may follow the blind administration of cardiac medicaments. Each functional disturbance requires an appropriate drug; thus auricular fibrillation is benefited by digitaline and still more by quinidine, while in treating disturbances of conduction digitalis should be withheld.

577. Bismuth Treatment of Syphilis in Children.

R. SOUTHBY (*Med. Journ. of Australia*, March 12th, 1927, p. 357) distinguishes three types of congenital syphilis in children: the early or florid type; the latent type, which becomes evident some years after birth; and the unsuspected type, which is only discovered by routine Wassermann tests. With the object of ascertaining whether treatment with bismuth alone was effective in children Southby treated 73 children with "bismol," an oily suspension containing 0.15 gram of bismuth hydroxide in 2 c.cm. of oil. Ten injections of the warmed preparation were given once a week intramuscularly into alternate buttocks, a second, third, or more courses following if the Wassermann reaction remained positive. Escape of oil was prevented by injecting it rapidly under pressure, when it seemed to diffuse more rapidly through the muscle. There was no interval between the courses unless the patient showed signs of bismuth intoxication, as evidenced by a gingival blue line, stomatitis, albuminuria, or the more severe symptoms of icterus, haemoptysis, rigors, and joint pains. The clinical and serological response to treatment was very good, especially in infants with the early congenital or florid type of disease; the rash, snuffles, and ulcerations rapidly subsided, and there was improvement in the general condition. Southby concludes that bismuth

treatment is apparently effective in obtaining a cure in children, the clinical manifestations subsiding rapidly; a longer period is required, however, to alter the Wassermann reaction than is the case with the arsenicals. The early congenital florid type was found to respond most rapidly and with greater certainty than the other types, and the local reaction at the site of the injection was much less than when arsenic is given. Toxic symptoms can be avoided by watching for the gingival blue line and by regular examination of the urine for albumin.

578. **Sanocrysin in the Treatment of Pulmonary Tuberculosis.**

N. OEKONOMOPOULO (*Acta Med. Scand.*, March 22nd, 1927, p. 1) discusses the findings of Moellgaard and his collaborators concerning the clinical application of sanocrysin. Moellgaard reported that this gold salt possessed great bacteriotropic properties, and that the severe reactions with fatal issues could be attributed to an intense toxaemia caused by the liberation of bacillary toxins owing to the bactericidal action of the salt. From the results obtained by Danish clinicians, Oekonomopoulo believes that the action of sanocrysin, favourable or otherwise, depends on the immuno-biological condition of the patient, the form of the lesions, and the age of evolution of the tuberculous process. The author reports the results of an investigation of thirteen cases treated by sanocrysin. He believes that the grave reactions and shock occurring in this method of treatment should be attributed to a metallic and not a biological intoxication, and that this salt possesses no sterilizing action, but exerts a toxic influence on the organism. He thinks that the use of sanocrysin is not dangerous if an appropriate dosage is employed and a judicious choice of patients exercised. The drug acts directly on tuberculous tissue by favouring the formation of cirrhotic tissue, and, though without absolute sterilizing powers, it has an indirect therapeutic action, and can effect relatively good results, which, however, are not stable.

579. **Ionized Tin in Furunculosis.**

IN view of his observation that tin miners are not subject to boils, G. B. MCAULIFFE (*Med. Journ. and Record*, April 20th, 1927, p. 547) decided to try tin applications in furunculosis of the ear, and found that this metal seemed to have a specific antagonism to staphylococcal infection when introduced beneath the surface of the skin. He used a mixture of metallic tin and its oxide, which was placed in solution in the ear; a current of 3 to 5 milliamperes was then applied for about ten minutes. Three daily treatments were given and rapid improvement followed, especially as regards the pain and inflammation. The author adds that the furuncle does not abort, but proceeds to painless maturation and discharge; the tin seems to relieve the pain of tension after the first treatment. When the boil is discharging he gives instillations of 5 per cent. mercurochrome, which he finds an efficient local antiseptic.

Anaesthetics.

580. **"Narco Local" Anaesthesia in Caesarean Section.**

F. E. KELLER (*Amer. Journ. Obstet. and Gynecol.*, February, 1927, p. 234) records nine cases, in patients aged from 20 to 41, of Caesarean section in which "narco local" anaesthesia was used, ether being contraindicated for the following reasons: chronic endocarditis and myocarditis with decompensation, chronic pulmonary tuberculosis, acute bronchitis, pyelitis with infection of the kidneys, hyperthyroidism, and nephritis with deformity of the symphysis. In the preparation of the patients no enema or purgative is necessary, and a dose of morphine sulphate, 1/6 grain, with scopolamine hydrobromide, 1/100 grain, is given one hour before operation. At the operation 0.5 per cent. novocain is administered by infiltration, an attempt being made to infiltrate the entire thickness of the abdominal wall before incising it. Keller thinks it is best to perform sterilization in selected cases at the time, thereby saving the patient the necessity of another operation either for ligation of the tubes or a therapeutic abortion in order to save her life.

581. **Scopolamine in Goitre Surgery.**

E. FISCHEL (*Anesthesia and Analgesia*, April, 1927, p. 100) maintains that the psychic factor in the induction of anaesthesia in goitre patients must not be ignored. Some have no dread of the operation, but are afraid of losing consciousness; others wish to be put to sleep before they see an instrument or the inside of an operating room; and others, again, overor under-estimate their ability to control themselves. Fischel advises that on first contact with the patient an attempt should be made to establish confidence, which will do much to quiet the overactive brain. Then come the usual sedatives, such as bromides, luminal, or veronal. Two days before the operation Fischel gives a test dose of scopolamine, one-half of that indicated for operative anaesthesia, in order to make sure that the patient will not be excited by the drug. A hypodermic injection of morphine combined with scopolamine is given one and a half hours before operation, the dose being determined by the degree of irritability of the nervous system and the weight of the patient. If only local anaesthesia is used Fischel gives 0.5 per cent. novocain with 3 drops of adrenaline (1 in 1,000) added to each ounce of the solution, infiltrating the tissues according to Braun's method. If an inhalation anaesthetic is given he uses the same novocain solution, but infiltrates only the line of incision. Nitrous oxide-oxygen is his inhalation anaesthetic of choice; it should be given to allay mental shock and to keep the patient sufficiently quiet to allow the operation to be performed. Ether is prescribed for patients with very high blood pressure and for those with obstruction of the trachea.

582. **Ephedrine as a Local Anaesthetic.**

IN order to obtain a local anaesthetic less toxic than cocaine and its allies B. E. READ and CH'IAO-CHIH LIN (*Chinese Journ. Physiol.*, January, 1927, p. 23) have tested various preparations by the wheal method of Sollmann. They found that a mixture of ephedrine with adrenaline and potassium sulphate produced as intense local anaesthesia as a similar mixture containing novocain in place of ephedrine. A definite synergism was shown to be caused by the mixing of ephedrine, adrenaline, and potassium sulphate, since ephedrine alone did not produce anaesthesia, though it was able to intensify slightly the anaesthetic action of novocain. The addition of 0.005 per cent. ephedrine to a 1 per cent. solution of novocain resulted in considerable shortening of the time taken in blocking the motor impulse along the sciatic nerve. The authors suggest that for dental surgery and ophthalmological work a mixture of ephedrine, adrenaline, and potassium sulphate may prove very valuable, especially since the relative toxicity of ephedrine is low, and it is stable, easily prepared and purified, and beneficial in conditions of shock.

583. **Brachial Plexus Block.**

E. M. LIVINGSTON and H. WERTHEIM (*Brit. Journ. Anaesth.*, April, 1927, p. 203) report the results of brachial plexus anaesthesia in 105 cases. They claim that it is suitable for any operation on the upper extremity, since its effects are limited to it and the vital centres are not affected. It has the advantage of allowing co-operation between the conscious patient and the surgeon, thus enabling the latter to dispense with an assistant in emergencies. If preliminary narcotics are used, the nerve trunks are avoided, and the operation is delayed until the full anaesthetic effect has been reached, as shown by the finger tips being insensitive to pain, operations can be performed without additional forms of anaesthesia. By the supraclavicular route of Kulenkampff 30 c.cm. of a 2 per cent. novocain solution are injected beneath the deep cervical fascia, usually through a single puncture; contact with the nerve trunks is avoided. No attempt is made to obtain paraesthesia, the solution rather than the needle finding the cords of the plexus. A hypodermic injection of 1/8 grain of morphine is given half an hour before the operation and repeated in some cases shortly before the brachial block is induced. In 102 of the 105 cases the operations were completed without additional means of anaesthesia. The authors state that the patient should be kept recumbent and under observation until the anaesthesia has passed away. Transitory complications, such as flushing, tremor, palpitation, and mild mental inco-ordination, occur in about 2 per cent. of cases, but they are of no greater severity than those following other methods of anaesthesia and never constitute a contraindication. Among operations performed under this method were those for infections and osteomyelitis of the forearm and hand, reduction of fractures and dislocations, repair of tendons and extensive injuries, removal of tumours and foreign bodies, amputation of the forearm, plastic operations, and median nerve suture.

Obstetrics and Gynaecology.

584. **Menstrual Haemorrhage and Health.**

B. ASCHNER (*Zentralbl. f. Gynäk.*, March 5th, 1927, p. 577) raises the question of menstruation being an excretory process. He believes that menstrual toxins are produced which, if the flow is arrested, scanty, or infrequent, give rise to symptoms of autointoxication. The presence of such toxins has not been confirmed chemically, but clinically their results are plainly seen. Abolition of menstruation, even in young women, leads to lasting disability, not only to passing

nervous and vasomotor disturbances, but to obesity, hyperaemia, raised blood pressure, gout, and rheumatism; such disabilities are commoner in normal or full-blooded women than in the small and anaemic. That these symptoms are probably due to retention and not to loss of ovarian hormones is indicated by the fact that they occur after hysterectomy when the ovaries have been retained. He suggests that less disturbance results from keeping part of the uterus and risking a return of any benign condition, and so maintaining menstruation, than by total removal. He adds that hysterectomy for an innocent condition should not be undertaken lightly because of the effect on the general health. Similar results are even more obvious in oligomenorrhoea and infrequent menstruation, classed together as hypomenorrhoea; here the retained products seek other paths, showing their results in diseases of the skin and eye, psychic disturbances, rheumatism, obesity, and polycythaemia. He urges strongly that the treatment should consist of emmenagogues and elimination of toxins, by diuretics, diaphoretics, salines, and, in suitable cases, venesection.

585. Treatment of Uterine Myoma.

ACCORDING to A. P. RAMOS and E. NICHOLSON (*Bull. Soc. d'Obstet. et de Gynécol. de Paris*, February, 1927, p. 89) the correct treatment for the great majority of cases of uterine myoma is surgical; radiotherapeutic measures should be reserved for patients who by reason of general disease, such as diabetes, cardiopathy, and tuberculosis, cannot tolerate operation. Their conclusion, which is shared by numerous other gynaecologists, is contrasted with the enthusiastic advocacy, about ten to twenty years ago, of *x*-ray and radium treatments, for which success was claimed in as many as 98 per cent. of cases. It is now acknowledged generally that *radiotherapeutic treatment of uterine myoma is contra-*indicated by pregnancy, inflammatory complications, malig*nant metaplasia, excessive size, and compression phenomena.* Apart, however, from these conditions, the authors state that *x*-ray or radium applications are certain to affect ovarian function, and much more often than not cause cessation of menstruation; while surgical treatment, with recent perfections of technique, in the majority of cases will permit retention of the ovaries and of menstruation. Reports from the Mayo Clinic show that about two-thirds of myomatous patients with medium-sized tumours show amenorrhoea after radiotherapeutic treatment; oligomenorrhoea only, as a result of careful gradation of dose, though theoretically attainable, is rarely achieved in practice. Myomectomy, as Goullioud states, is the only operation permitting the patient to retain her physical, intellectual, and moral value. Ramos and Nicholson believe that over 80 per cent. of myomatous subjects are amenable to this conservative treatment; they have so far had no cases of post-operative recurrence of symptoms, and quote the finding of Aschner, whose 47 patients, with two exceptions, had five years' freedom from recurrence after myomectomy. In cases in which myomectomy is too difficult or complex, Ramos and Nicholson utilize, when possible, Freund's cuneiform hysterectomy, with conservation of sufficient endometrium to preserve the function of menstruation.

586. Caesarean Section in Eclampsia.

L. TOMASI (*Il Policlinico*, Sez. Prat., April 11th, 1927, p. 526) records twelve cases of Caesarean section in eclampsia and advocates its more general use in this condition. He agrees that when the os is well dilated and the head advanced more ordinary means of delivery should be used; but when eclampsia sets in early in labour with a rigid undilated os, unbroken membranes, and a living child, Caesarean section is preferable, being the most rapid way of emptying the uterus. Alternative methods, such as turning, mechanical dilatation of the os, and forceps, introduce the risks of sepsis, injury to the soft parts, and delay; section, on the other hand, is rapid and in suitable conditions not very risky, the narcosis serving to diminish the convulsions.

Pathology.

587. The Process of Immunization.

H. D. WRIGHT (*Journ. Path. and Bact.*, April, 1927, p. 185), investigating antipneumococcal immunity in rabbits, found that a single intravenous injection of 5 c.cm. of a killed culture of pneumococci conferred on the animal a greatly enhanced capacity of removing a subsequent dose from the circulation, and of suppressing completely or in part the subsequent increase of the organisms. When a non-lethal dose of pneumococci was injected intravenously, it was found that the organisms diminished in numbers in the blood for about five hours; after this time they started to multiply to a variable extent, and then underwent a second diminution in numbers, leading to their complete disappearance in three or four days. If a lethal dose was injected, the same preliminary diminution in numbers occurred, but after this the organisms multiplied progressively and led to the death of the animal. If a virulent organism was injected intravenously into a rabbit which has recovered from a non-lethal dose of pneumococci, of which had received a formolized vaccine or a pneumococcal autolysate, the preliminary diminution in numbers was greatly augmented, so that the subsequent increase might fail to occur. Wright concludes that the clearing capacity of the immunized animal is considerably greater than that of the normal animal, and adds that the development of this increased clearing capacity may be detected as early as five hours after the immunizing dose; it is very marked after three days, and may persist for as long as ten months. It is both species- and type-specific. No definite association could be determined between this capacity and the production of antibodies such as agglutinins, precipitins, or opsonins. If this capacity was dependent on the production of an antibody, either this antibody must be of a new order hitherto undescribed, or the antibodies at present known must be capable of acting in the living body at a very much higher dilution than *in vitro*. That it was a true humoral antibody seemed to be proved by the fact that the increased clearing capacity could be transferred to a normal rabbit by means of the serum of an immune animal. How this antibody acted was not ascertained, but there was evidence suggesting that it favoured phagocytosis. Diminution of the circulating leucocytes by injection of benzol, and blocking of the reticulo-endothelial system with indian ink or lithium carmine, did not interfere with its action. The author also found that the blood of an immunized rabbit *in vitro* destroyed virulent pneumococci or delayed their growth; and he observed that this property appeared earlier and lasted longer than any other antibody activity tested. It would appear, however, that the ability of the whole animal to destroy virulent pneumococci is very much greater than that of the blood alone. The author considers that the clearing mechanism is dependent on a complex series of factors involving phenomena of adhesion and phagocytosis by mutually complementary systems of cells.

588. Bacteriolysis of B. tuberculosis by Living Tissue.

C. RICHET, JUNR. (*C. R. Soc. de Biologie*, April 26th, 1927, p. 965), has continued his experiments on the bacteriolytic action of the tissues on Koch's bacillus. A piece of tissue, weighing about half a gram, was removed aseptically and placed in a tube containing 5 c.cm. of sterile saline solution. A thin suspension of a human strain of tubercle bacillus was prepared, to contain about one organism per field of the microscope after it had been added to the tissue. The mixture of tissue and bacilli was examined every day for about a fortnight, and the number of organisms visible was noted. Using liver, spleen, or muscle removed from a rabbit that had been bled to death, the author found that the bacilli generally diminished in numbers and often disappeared completely. Thus in sixteen experiments disappearance of the organisms was recorded in ten, a diminution in four, and no effect in the remaining two. Injection of some of these mixtures into guinea-pigs was performed. Five of the mixtures, in which raw tissue had been used, proved innocuous, but two, in which the spleen and liver had been previously heated, gave rise to tuberculosis. Further experiments were made with similar results on the tissues of guinea-pigs. The author concludes that the liver, spleen, and muscle tissue of the rabbit, and the liver tissue of the guinea-pig, exert a bacteriolytic action on tubercle bacilli *in vitro*, and that the principle responsible for this lysis is thermolabile.

589. Nematode Parasites and the Etiology of Cancer.

A. BORREL (*Bull. l'Assoc. Française pour l'étude du Cancer*, February, 1927, p. 126) recalls his previous observations on the association of rat sarcoma of the liver with the cysticercus of *Taenia crassicula* of the cat, which, he states, was confirmed experimentally in America by feeding rats with ova of this nematode. He raises the question whether the cysticercus acting as an irritant is able to cause a cancer to grow, or if it is only the carrier of a virus. Borrel has often found a filaria in association with mammary growths in the mouse; the worms were discovered either within the tumour or in its near neighbourhood. On several occasions he observed living threadworms containing mature embryos in early formed very small growths 1/2 to 2 mm. in diameter. He considers that the presence of the living parasite is only transitory, and that if the mice had been killed two or three days later no living filaria would have been found. He suggests that some ectoparasite inoculates the mouse with the filaria; in certain periods of the year fleas are very abundant in the breeding cages and he has found young filarial embryos in the subcutaneous tissue of the mice: the question whether a virus may be carried by the parasite is raised.

EPITOME OF CURRENT MEDICAL LITERATURE.

Medicine.

590. Measles Prophylaxis by Convalescent Serum.

KARELITZ and S. LEVIN (*Amer. Journ. Dis. Child.*, March, 1927, p. 403) review the literature and record their own observations on the prophylactic treatment with convalescent serum of children exposed to measles. Their conclusions are as follows. (1) Children under 2 years of age, those suspected of having tuberculosis, infants in hospitals or nurseries, and others in whom measles would be a dangerous complication should receive complete passive immunization. All others could be benefited more by small doses or late injections, which would lead to a mild modified form of measles, probably causing permanent immunity. (2) Convalescent serum has the greatest immunity titre from six to ten days after the temperature has reached normal. Adult donors should be free from tuberculosis, syphilis, and other transmissible disease, and they must have had measles. (3) For complete protection of a child up to 3 years of age, who has been exposed from one to four days, 5 c.cm. of convalescent serum, 5 c.cm. of adult serum, or 75 c.cm. of adult whole blood is given intramuscularly. If exposed from five to seven days the same child should have 10 c.cm., 30 to 40 c.cm., or 75 to 100 c.cm. of convalescent serum, adult serum, or whole blood respectively. For a child aged 3 years and over the dosage after exposure of from one to four days is 10 c.cm., 30 to 40 c.cm., or 75 to 100 c.cm. After five to seven days' exposure the same child should receive from 15 to 20 c.cm., 30 to 40 c.cm., or 100 to 200 c.cm. For production of modified measles, one-third to one-half these doses is given. (4) Of 75 patients exposed to measles 3 not treated had typical attacks, 11 of 60 treated with convalescent serum had a very modified form of the disease, and 3 of 14 treated with adult blood or serum had more severe forms of the modified disease; 2 of the last 3 received transfusions from donors who had never had measles. (5) Modified measles is characterized by prolonged incubation periods of from twelve to thirty-one days, mild or absent invasion period, mild or absent coryza and photophobia, no or few Koplik's spots, mild prodromal rash, little or no eruption, very mild constitutional reaction, and no complications.

591. Asthma Simulating Tracheal Stenosis.

C. SCHWARZER (*Zentralbl. f. Chir.*, April 2nd, 1927, p. 857) describes the case of a primipara, aged 21, who, towards the end of pregnancy, had a sudden attack of dyspnoea with loud stridor; there was a moderately large goitre, and a diagnosis was suggested of tracheal stenosis due to pressure of the goitre. The patient was very cyanosed, and a loud stridor persisted. Schwarzer was not convinced that the goitre was sufficiently large to produce dyspnoea, and a skiagram showed that there was no tracheal stenosis. He also observed that the stridor occurred during expiration only, and auscultation revealed the presence of râles and rhonchi, confirming his opinion that the patient was suffering from severe asthma. She was relieved by treatment with daily injections of calcium and adrenaline. Shortly afterwards she was delivered spontaneously and painlessly, and there was no recurrence of the asthma. Schwarzer emphasizes the necessity for very careful examination of these cases before any operative procedures are undertaken.

592. Tuberculous Endocarditis.

ACCORDING to A. PIC and L. MORENAS (*Journ. de Méd. de Lyon*, April 20th, 1927, p. 185) there is a form of tuberculous endocarditis of inflammatory nature which is characterized by sclerosed cicatrices in the parietal or valvular endocardium. It is believed to be a cause of many cardiopathies of adults, particularly the so-called congenital mitral stenoses. The authors state that this condition may occur at any age, but is mostly seen in children and adolescents; it has been found in the newborn, infection having possibly been transmitted from a tuberculous mother by filterable viruses through the placenta. Rheumatic endocarditis is said to be a predisposing factor, as is also tuberculosis in other parts of the body. The authors recognize four groups of tuberculous endocarditis. (1) The vegetating, in which the lesions can be very extensive and involve especially the valves of the left cavities. They resemble those of the rheumatic type, but in the tuberculous form the vegetations are more strictly localized on the valves, the fibrinous coagulum is less thick, and the inflammatory lesions less extensive. (2) The attenuated inflammatory type, in which the two auriculo-ventricular valves are affected, and especially the mitral. This form is found in bacillary septicæmia. (3) The fibro-calcareous type, in which the mitral orifice is enclosed in a quasi-osseous ring; this form is very rare. (4) The sclerosed type, in which the sclerosis may be generalized over the valves and myocardium, or may be localized in one valve. The authors add that tuberculous endocarditis may be associated with pericarditis and myocarditis, and may cause symptoms of cardiac insufficiency. Its diagnosis is practically presumptive. The relative youth of the patient, possible infection from an adjoining tuberculous focus, the finding of Koch's bacillus in the blood, and collateral and hereditary tuberculous antecedents are the chief diagnostic points. No specific treatment is known. Simple inflammatory forms often heal spontaneously, while septic cases end fatally. In children preventive measures may be supplemented by the administration of Calmette's and Guérin's vaccine; in an already established endocarditis the treatment is that of tuberculosis elsewhere.

593. Optic Neuritis in Scarlet Fever.

HAKEN (*Münch. med. Woch.*, March 25th, 1927, p. 495), who records three illustrative cases, states that Groenow collected eight cases from the literature. Among 253 cases of optic neuritis occurring in infectious diseases Uhthoff found that only three were due to scarlet fever. A case reported by Barlow showed symptoms of nephritis. In Betke's patient there was evidence of neuritis. None of the other cases showed any further complications. The margins of the papilla were in all cases indistinct and deformed, in some cases choked disc was present, and others showed haemorrhages and neuro-retinal changes in the fundus. Two cases recovered, two showed considerable improvement, and one ended in optic atrophy. Haken's cases all occurred in a Berlin hospital in the spring of 1926. Two were women, aged 21 and 25 respectively, and one a man aged 36. In all three cases the attack of scarlet fever was severe and complicated by myocarditis, but none had any albuminuria. Visual capacity and perception of colour were considerably diminished in all. Ophthalmoscopic examination showed at first redness and deformity of the papilla with dilatation of the vessels, the latter persisting for a long time after visual capacity had been regained. Complete recovery followed in two or three weeks. In one case meningitis could not be excluded; in two there was otitis media. The sinuses in all the cases were intact.

Surgery.

594. Primary Hydatid Disease of the Omentum.

G. CIAPRINI (*Il Policlinico*, Sez. Prat., April 4th, 1927, p. 489), who records an illustrative case, states that while secondary involvement of the omentum is fairly frequent after spontaneous or provoked rupture of hydatid cysts in intraperitoneal organs, especially the liver, primary hydatid disease of the omentum is very rare. According to Aimes only 32 cases had been described up to 1920, and to these must be added one reported by Bolognesi and two by Margarucci in 1923. Ciaprini's case, which appears to be only the thirty-sixth on record, occurred in a soldier, aged 20, who since the age of 15 had suffered from abdominal pain, which had recently become localized in the right lower quadrant. On examination a hard movable swelling the size of a mandarine orange was found about two fingerbreadths to the right of the umbilicus. A diagnosis of chronic appendicitis and partly calcified mesenteric adenitis was made. At operation three hydatid cysts were found in the omentum and removed. The liver and appendix were normal and no cysts were found elsewhere. An *x*-ray examination of the thorax was negative. Subsequent recovery was rapid and uneventful.

595. Diseases of the Thyroid Gland.

A. S. JACKSON (*Amer. Journ. Surg.*, March, 1927, p. 228), in discussing diseases of the thyroid, draws attention to the fact that it is not always easy to diagnose cases of hypothyroidism; a patient who is above average weight, whose skin is dry, and whose powers of cerebration are slow should be suspected in this connexion. Cold weather causes suffering in these cases and the basal metabolic rate is slowed. Thyroxin given intravenously causes rapid improvement and after this thyroid given by mouth. Adenomata frequently develop in colloid goitre as a form of compensatory hypertrophy. Iodine does no good and may do harm in these cases

after the age of 20 years. Adenomatous goitres are potentially malignant and should be removed; they do not become toxic before the age of 30. They invariably develop before the age of 20; hyperthyroidism only occurs slowly in these cases, and the true condition may not be noticed at first. Conversely exophthalmic goitre is characterized by a rapid onset which seldom exceeds three months. The appetite of these patients is frequently ravenous, which is a valuable diagnostic point. Tachycardia and increased basal metabolic rate are always present. Jackson considers that surgical treatment in these cases has been revolutionized by the use of iodine before operation. With proper preparation the mortality after operation has been reduced to 1 or 2 per cent. or even less. These cases may be operated on with excellent results, particularly if the disease is treated early.

596. Tuberculosis of the Tongue.

J. RICHARD (*Thèse de Paris*, 1926, No. 521) states that tuberculosis of the tongue is a polymorphous affection of which the following varieties may be described: (1) Tuberculous ulceration. This is the commonest form, which is met with in adult life, and in the majority of cases is secondary to pulmonary tuberculosis. Primary ulceration is much rarer, but undoubtedly does occur. (2) Tuberculous gumma. This is a rarer form, of which only forty cases have been recorded. Primary and secondary forms are equally common. The prognosis is better than that of tuberculous ulceration, as it is more frequently primary. (3) Lupus vulgaris. This is an affection of adolescence, and is always associated with lupus of the face or nasopharyngeal mucosa. It is situated usually at the base of the tongue and may assume a papillomatous, ulcerative, or mixed form. (4) Lupus erythematosus is a still rarer variety, of which only eight cases have been recorded. Like the previous variety, it has always been associated with facial lesions. It appears in the form of erythematous, occasionally infiltrated, patches, which are partly or entirely concealed by scar tissue resembling leucoplakia or lichen planus. (5) The papillomatous form, of which ten cases have been recorded, differs from the two previous varieties by existing independently of lupus of the face or adjacent mucosa. It is an affection of adult life often secondary to pulmonary tuberculosis, and is situated by preference on the middle part of the dorsum of the tongue in the form of a round or oval tumour. It is readily cured by surgical treatment.

597. Thrombo-Angiitis Obliterans.

J. A. SICARD (*Bull. et Mém. Soc. Méd. des Hôpitaux de Paris*, April 7th, 1927, p. 443) describes, under the title of Buerger's disease, a form of arteritis occurring in young men. It runs a steady progressive course, attacking first the extremities of the lower limbs and then extending to the extremities of the upper limbs. It is accompanied by a moist inflammatory reaction, but does not proceed to a dry gangrene because the venous thrombosis is almost always associated with arterial thrombosis. It is resistant to all forms of medical and physical treatment, and surgical intervention is always needed. Pain is relieved immediately by amputation, after which the skin incision heals by first intention. Death supervenes from some intercurrent complication, usually of pulmonary origin. The disease is said not to occur in women; it is especially found among Russian Jews, Poles, Rumanians, and Japanese. On this account, and particularly from its sex selection, the author thinks that it is connected with some endocrine condition, such as the insufficient or defective secretion of adrenaline, which more especially affects the distal arterioles owing to their feebler resistance. The author refers to successful results obtained by removal of one of the suprarenal glands, and since the suprarenal glands are actuated by a testicular hormone he suggests that these cases should be feminized. Failing ovarian grafts or testicular radiotherapy he advocates daily subcutaneous injection of 10 c.cm. of woman's blood and of 4 to 5 grams of parovarian extract. He claims by this treatment to have postponed the necessity for operation and to have limited the focus of the inflammation.

598. Pseudarthroses.

B. PFAB (*Deut. Zeit. f. Chir.*, March, 1927, p. 271) states that during the period 1920–25 among 433 fractures of the leg bones and patella admitted to the Orthopaedic Hospital at Graz there were 40 cases of pseudarthrosis, which were classified as follows: tibia and fibula 18 cases, forearm 7, tibia 5, neck of femur 4, upper arm 4, patella 1, finger 1. No pseudarthoses in the femur were observed. Operations were performed on 34 patients, of whom 76.4 per cent. made a complete recovery. Ether anaesthesia was used, and the subperiosteal ends of the fracture were exposed, special care being taken to bring the ends together and to open the medullary cavity. Steel wire or kangaroo tendon was employed for uniting the fragments.

Therapeutics.

599. Treatment of Neuro-syphilis.

S. HECHT (*Med. Journ. and Record*, March 16th, 1927, p. 403) agrees that the characteristic headache of syphilis indicates a specific meningitis; he has seen cases in which the cerebro-spinal fluid gave a positive reaction six weeks after the appearance of the chancre. Every syphilitic should be regarded as a potential neuro-syphilitic. He doubts whether a patient can be cured in less than three years by modern treatment; even then he is not absolutely sure of the permanency of the results. He finds neosalvarsan quite as active and far less dangerous than old salvarsan. Freshly distilled water should always be used, since many, if not all, reactions are due to stale or impure water. A routine examination of the heart and urine should always be made, a good aperient be given on the previous night, and the patient should have no food for four hours before the injection. Hecht prefers silver salvarsan given intravenously in doses of 0.15 to 0.2 gram every five days; he finds it efficacious and prompt in action where old salvarsan or neosalvarsan has failed, and much less prone to cause reactions. He describes three cases of severe lightning pains and gastric crises in tabetics who were much improved and rendered able to attend to business after treatment by this salt after the older remedies had failed. He considers it the best remedy for neuro-syphilis, and thinks it should be given in courses of eight to ten injections at intervals of five days. He agrees that mercury has not been superseded by salvarsan, but he dislikes mercurial ointment and prefers insoluble preparations, such as mercury salicylate (20 per cent.) in oil, which is injected every five days. Twelve of these injections are given after the course of silver salvarsan unless bismuth is included in the treatment, in which case six mercury injections are followed by six intramuscular injections of an insoluble bismuth preparation at intervals of five days. Hecht states that bismuth is but slightly superior to mercury; it has the advantage of being practically painless, and in some cases its use is followed by better results than those of the older remedies. He gives eight or ten intravenous injections of silver salvarsan at intervals of five days, and six intramuscular injections of bismuth. After a month's rest the course is repeated in the same order. This is continued for a period of three to five years, disregarding the serological reactions. He employs spinal drainage following the intravenous injection of salvarsan to promote the flow of arsenic into the newly formed spinal fluid, and adds small quantities of salvarsan (1 to 2 mg.) to spinal fluid which is reinjected into the spinal canal. He condemns tryparsamine, but approves of the malarial treatment of neuro-syphilis by intravenous injections of 2 to 5 c.cm. of blood from a tertian case. After ten attacks of fever the patient is given quinine for two months and then has a course of ordinary anti-syphilitic treatment. Malarial treatment was tried in eight cases which had been treated intensively by other methods without result. Of these, five were greatly improved, and, after being bedridden, regained power to walk. He finds that malarial treatment is only efficacious in those patients who develop high fever.

600. Treatment of Tuberculous Empyema.

G. CAUSSADE and A. TARDIEU (*Bull. Soc. de Thér.*, March 9th, 1927, p. 70) record four cases of tuberculous empyema, in patients aged from 16 to 45, treated by intrapleural injections of a mixture of the following composition: iodoform 1 gram, sulphuric ether 10 c.cm., and 25 per cent. solution of ethyl morrhuate in olive oil to 100 c.cm. The object of the treatment was to combine the antiseptic action of iodoform with the local and general chemotherapeutic action of cod-liver oil as well as with compression of the lung. In three cases complete recovery, and in one considerable improvement, resulted from the treatment, which was continued from three to six months.

601. Treatment of Snake-bite.

H. WADA (*Japan Med. World*, February 15th, 1927, p. 35) has made a series of experimental investigations of the treatment of snake-bite by potassium permanganate and hydrogen peroxide, both of which were found to destroy *in vitro* the toxicity of the venom of the *Agkistrodon* snake; rabbits were employed in the investigations. It was shown that, after being bitten by the snake, the animals could be saved if 1/2 to 1 per cent. permanganate solution was injected into the wound within seven hours; the action of this venom is chiefly local. Injections of hydrogen peroxide solution were found to be similarly effective if given within nine hours of the snake-bite; no local injury other than slight haemorrhages was caused by this solution. Subcutaneous injections of lobelin and camphor were found to prolong life, but not to cure

the condition; repeated injections of these two drugs assisted the action of potassium permanganate or hydrogen peroxide and helped to save life. Local intravenous injections of calcium chloride (recommended by Kobayashi) were found to have no curative action, and this salt did not destroy the venom *in vitro*.

602. **Calcium Salts in Epilepsy.**

As the result of treating twenty-seven epileptics, fourteen with intravenous injections of calcium chloride and thirteen with injections of gluco-calcium, a product of glucose and calcium, E. KLEIN and E. FORCIONE (*Journ. Nerv. and Ment. Dis.*, April, 1927, p. 372) conclude that no benefit is derivable from the use of calcium in epilepsy. They add that the number of seizures shows a tendency to increase, and also that there is no advantage in the use of gluco-calcium over calcium chloride. No sustained increase in the calcium concentration of the blood serum was found after the injection of 1/2 to 2 grams of calcium salts.

Neurology and Psychology.

603. **Disorders of Conduct in Children.**

I. S. WILE (*Journ. Amer. Med. Assoc.*, April 16th, 1927, p. 1222) reviews the more common causes of disorders of conduct in children and warns against limiting treatment to the obvious condition, which is often only symptomatic of deep-seated trouble. He states that in all emotional outbursts it is necessary to distinguish between the factors preceding the *disturbance and the subsequent manifestations*. Among the contributing causes which must be assessed are inherited tendencies, physical and functional defects, failure in adaptation to environment, and parental overcontrol or neglect; an abnormality may be due to one or more of these. He adds that it is useful to ascertain whether conduct disorders are occasional, periodical, or habitual. Problems arise from the fact that the child is a human as well as a physical being, and it is necessary to realize that society plays a part in creating the difficulties of individuals. The child must, therefore, be carefully studied in his environment, and not apart from it, and mental deficiency is not to be considered more important etiologically than superiority of intellect. Wile *thinks the psycho-analytical method of approach is* valuable, but he does not champion any specific theory of psychic action. There is, he adds, little excuse for the assumption of *universal Oedipus and Electra complexes*. A fixed belief in constitutional inferiority as a cause is little more helpful than the view that conduct is a predetermined phenomenon of behaviour. *Each child needs a rational and* individual study, and treatment must be directed to both the patient and the environment.

604. **Nervous Manifestations of Helminthiasis.**

J. ZAMIA (*Thèse de Paris*, 1926, No. 440), who records seven illustrative cases in patients aged from 14 to 35, five of which are original, states that the nervous phenomena observed in the course of intestinal helminthiasis are due to two causes: (1) mechanical irritation of the mucous membrane of the intestine, (2) toxic disturbances due to the secretions of the parasites. The latter alone are of clinical importance. The mechanical disturbances are transient and usually precede or accompany the expulsion of the worms. The toxic disturbances, on the other hand, are of gradual onset, protracted and difficult to diagnose. One of the most important forms is helminthic meningitis, which is accompanied by chemical and cytological changes in the cerebro-spinal fluid. The possibility of its occurrence should always be considered in the presence of a meningeal syndrome. Another nervous manifestation of helminthiasis is neurasthenia, which is characterized by anxiety and headache, most pronounced at night. The presence of such a syndrome should indicate examination of the stools.

605. **Diffuse Cortical Sclerosis.**

G. Y. RUSK and C. E. NIXON (*Journ. Lab. and Clin. Med.*, April, 1927, p. 644) state that, in addition to the secondary cortical scleroses, there is a distinct form, commonly found in children, which is of unknown origin, and is associated with diffuse cortical atrophy and sclerosis. They cite several cases described by other observers, and report two further cases, both in children, one aged 2 years and 10 months, the other 1 year and 5 months. In both cases the family and antecedent history was negative, and the vision was affected. Hearing was definitely involved in the second case and probably also in the first. The first child was definitely rigid, with exaggerated deep reflexes when first seen, but these diminished later; the second was spastic, and also had exaggerated reflexes. Macroscopically, the brains showed a striking diffuse symmetrical atrophy of the convolutions, with wide, shallow sulci. There was an intense hypertrophy of the glial tissue in the cortex, and to a much less extent in the white matter of the brain, the basal ganglia, the brain stem, and cord, with marked involvement of the cortical nerve cells. All types of glia cells were seen, and there was a marginal

re
's
t.
er

these changes were much more marked, and satellitosis and neuronophagia were also present. The myelin sheaths in the first brain showed little abnormality, but in the second these were markedly involved. The meninges in the former contained a thick overgrowth of connective tissue, but in the latter there was only a thin, delicate membrane associated with a marked external hydrocephalus. Neither brain showed inflammatory changes. The grey matter of the cortex in both cases was evidently primarily involved, and the authors think that the condition represents a primary disease of the nerve cells with secondary glial hypertrophy. The absence of inflammatory processes and changes in the blood vessels preclude a vascular origin, and the disease is most likely an agenetic condition.

606. **The Neuropathology of Acute Chorea.**

L. H. ZIEGLER (*Journ. Nerv. and Ment. Dis.*, March, 1927, p. 273) reports a case of acute chorea with the necropsy findings in view of the doubtful etiology and pathology of this disease consequent upon the paucity of histological evidence. There is admittedly some relation between chorea, endocarditis, and rheumatism, and choreic movements have been observed in other conditions, such as pregnancy and the puerperium, gastro-intestinal diseases, exophthalmic goitre, polycythaemia, and acute epidemic encephalitis. The pathological findings in acute chorea have been so varied that a proved and definite lesion is unknown. Recent work points *especially to toxic changes in the brain cells and to destructive* lesions of the corpus striatum, some of which resemble the lesions of epidemic encephalitis. In Ziegler's case the chorea was associated with acute endocarditis. There was chromatolysis of practically all the cells of the central nervous system, with swelling of the nuclei and eccentric displacement. Some neurons were destroyed, especially in the sixth nerve and calcarine cortex, where glia cells were much proliferated. Other conditions present were neuronophagia; fatty deposits in the large cells of the motor cortex and pallidum; fat in the perivascular spaces; and petechial haemorrhages in a small area near the dorso-medial aspect of the restiform body of the medulla. Ziegler suggests that in this disease some of the elements of the brain may be less resistant to toxins or infections, which may, alternatively, have an elective action (irritating to destructive) on certain areas of the brain. Though recovery from the disease is possible, yet certain morbid tendencies observed in those who have had chorea make it apparent that the motor system has never developed properly, or that there are slight residual effects.

Obstetrics and Gynaecology.

607. **Rectal Analgesia in Obstetrics.**

J. WALKER (*Med. Journ. and Record*, April 6th, 1927, p. 474) discusses the relative value of the different analgesic methods in obstetrics and the indications for their use. He concludes that the nearest approach to the ideal of painless childbirth is afforded by that originally advocated by Gwathmey—*namely, rectal analgesia with ether, morphine, and magnesium* sulphate. At the onset of labour the bowel is emptied by a simple enema. When the pains are occurring every three to five minutes and lasting about half a minute, and the cervix is about the size of a five-shilling piece, an intramuscular injection of 1/6 to 1/4 grain of morphine sulphate in 2 c.cm. of a 50 per cent. magnesium sulphate solution is given, preferably during a pain, into the gluteal region. The patient is then kept very quiet, and half an *hour* later a second injection of 2 c.cm. of the magnesium sulphate solution alone is given. If there is no relief in twenty minutes the ether instillation is administered. With a gloved finger in the rectum the end of a catheter is directed beyond the foetal head, vaseline being *applied to the anus to prevent* burning by any escaping ether. An ounce of warm olive oil is poured through a funnel into the catheter and then the ether mixture, consisting of quinine hydrobromide 20 grains, alcohol 3 drams, ether 2½ ounces, and olive oil to 4 ounces, is given, followed by another ounce of warm olive oil. The administration of this instillation should extend over a period

of from ten to fifteen minutes; it should occur between the pains, and may be followed by another injection of magnesium sulphate solution. The success of the treatment depends upon judgement in giving the initial injection and the time of instillation; it appears to act best in primiparae and in those who are inclined to be nervous. All the patients slept for several hours after delivery, and did not show the signs of fatigue seen in those delivered by other methods.

608. The Capillary Circulation in Eclampsia.

T. HEYNEMANN (*Zentralbl. f. Gynäk.*, February 26th, 1927, p. 518) has found as the result of five years' trial that the use of the capillary microscope is of considerable practical value in eclampsia and the pre-eclamptic state. The alterations noted fall as a rule within two main groups: in the first the capillary circulation shows quickly and almost rhythmically alternating conditions of flow and stasis, while the second is characterized by repeated stases which may last one or even several minutes. The latter group is noted most frequently after serious operative interventions. Heynemann speaks with considerable reserve of the diagnostic utility of capillary microscopic observation. He states that the changes seen in eclampsia are also encountered in many normal pregnant women, and especially in healthy parturients; also that some cases of eclampsia are not associated with any morbid microscopic findings in the capillaries. The value of the method is chiefly prognostic, and it provides an index of the success or failure of therapeutic measures. For example, if the capillary circulation has temporarily improved after venesection, renewed signs of impairment may indicate the induction of abortion. With continued improvement of capillary circulation after bleeding narcotics are indicated if the circulation shows rapidly alternating streaming and stases; cardiotonic and stimulant measures are required if the circulation is of the type showing prolonged stases. Heynemann does not consider it justifiable to regard the alterations in capillary circulation as causative of an eclamptic convulsion, even supposing that conditions similar to those in the skin exist in the central nervous system; it is possible that they are merely an associated phenomenon.

609. Insulin in the Vomiting of Pregnancy.

E. SACHS (*Med. Klinik*, April 15th, 1927, p. 556) has found insulin treatment successful in severe cases of the vomiting of pregnancy when patients were losing weight and rejecting food. He begins with small injections of 5 units twice a day and progresses to two daily doses of 20 units. These doses are not preceded by the administration of carbohydrates, and it is to this that he believes the efficacy of the treatment is due. Symptoms of hypoglycaemia have never appeared. The improvement is immediate; the patients cease to vomit, their appetite improves, and they gain in weight. The mode of action is obscure, but the author holds that since the causation of the disease is possibly psychological, its treatment along the same lines—namely, by the administration of a popular drug—is at least justified by the results.

Pathology.

610. The Virus of Pleuropneumonia.

J. ORSKOV (*Ann. de l'Inst. Pasteur*, April, 1927, p. 473) has studied three strains of the pleuropneumonia virus. The medium used for cultivation was serum agar or ascitic agar; on both of these good growth occurred, with the formation in three to five days of colonies visible to the naked eye. To study the morphology of the organism the author examined growing colonies under the microscope, using the ordinary agar block method. With a small arc lamp as his source of illumination, an immersion lens, and a high compensating ocular, he obtained a clear image of the actual organisms; he was thus able to dispense with the use of the dark background. The morphology of the three strains was not identical; two of them were closely similar, but the third strain showed noticeable differences. He states that, generally speaking, the early or elementary form consists of a small oval body or a short rod; as this grows it forms a ramified mycelium, which later undergoes division into the small elementary forms. The organism, however, appears to be highly pleomorphic; at the edge of a growing colony, after four days' incubation, it was possible to distinguish a number of very irregularly shaped, branched and unbranched bodies, together with small, almost streptococcal forms, and rods constricted at the equator. The large swollen forms are probably the result of degeneration; for if cultures containing many of these forms are transferred to a fresh medium no growth occurs. In cultures aged about twenty to thirty hours one strain showed colonies having a central more compact portion surrounded by long streaming filaments, often with slightly nodular ends. The colonies formed by the other two strains had shorter filaments; moreover, after incubation for about two days autolysis became very active, so that the elements were transformed into swollen vesicles looking not unlike a hydatidiform mole. These large swollen forms were no longer capable of reproduction; this process depended exclusively on the small elementary forms of the organism. The author adds that while his observations agree with those of Bordet and others, they differ from those of Barnard.

611. The Intradermal Salt Solution Test in Scarlet Fever.

BEATRICE R. LOVETT (*Amer. Journ. Med. Sci.*, April, 1927, p. 539), after performing a series of intradermal salt solution tests on sixty patients with severe scarlet fever, concludes that the time of disappearance of the wheal is shortened in this infection, the shortening being proportional to the severity of the illness. If the disease progressed without complications, the duration of persistence of the wheal decreased rapidly, the normal being reached usually before the patient was in a fit state to get up. Urticaria was usually found to be associated with a shortened disappearance time. The author adds that an interval of less than thirty minutes before the wheal vanishes may be taken as an additional indication for giving scarlet fever antitoxin.

612. The Sedimentation Test in Appendicitis.

A. VIOLATO (*Rif. Med.*, March 14th, 1927, p. 248) refers to the findings of Starlinger that the plasma of persons whose red blood cells have a raised rate of sedimentation is richer in fibrinogen and globulin than normal plasma, and that this increase in fibrinogen is associated with increased disintegration of albumin in the tissues, there being a correlation between destructive organic processes and raised velocity of red cell sedimentation. Other workers have found that the red blood cells have a negative electrical charge, whereas fibrinogen and globulin have a positive electrical charge, and that the varying proportions of these charges determine the varying sedimentation rates of the red cells. In cases of acute infection of chronic inflammatory conditions accompanied with wasting such as tuberculosis, the sedimentation rate is raised. Using the method of Katz, details of which are given, the author has observed the red cell sedimentation rates in 103 cases of appendicitis, presenting various clinical appearances. In all cases, especially in those accompanied with suppuration or periappendicular abscess, the sedimentation rates were raised, but fell immediately after operation and gradually returned to normal with healing of the operation wound. This increased velocity of red cell sedimentation was associated with a corresponding rise in the number of the polymorphonuclear leucocytes. It is concluded that the estimation of the sedimentation rate is a useful means of determining the presence of an intraperitoneal suppuration.

613. Renal Function Tests in Prostatic Enlargement.

L. LURZ and HAMMEL (*Deut. Zeit. f. Chir.*, March, 1927, p. 200) consider the amount and concentration of the urine excreted during the first four hours after the administration of 1½ litres of fluid, such as weak tea, as one of the most valuable tests of renal efficiency when prostatectomy is contemplated, except in cases of complete retention. The difference between the lowest and highest specific gravities of the specimens obtained during the test should be not less than 15, and the kidneys should be capable of excreting urine of a specific gravity of less than 1006. This test should be used in conjunction with cystoscopy, the indigo-carmine excretion test, and the estimation of the residual urine, the blood pressure, and the residual nitrogen in the blood. Prostatectomy is contraindicated if the blood pressure exceeds 160 mm. of mercury after preliminary treatment.

614. Blood Changes in Scarlet Fever.

A. TÜDÖS and P. KISS (*Jahrb. f. Kinderheilk.*, April, 1927, p. 356) examined the fibrinogen in twenty-eight cases, the total albumin content of the serum in twenty-one cases, and the residual nitrogen in thirteen cases of scarlet fever, and came to the following conclusions. In the initial stage of scarlet fever a rise of fibrinogen is characteristic; in uncomplicated cases there is later a gradual fall. This rise serves as a delicate guide to complications and in some cases is perceptible even before these develop. The total amount of serum albumin is often increased, but this cannot be utilized as a prognostic sign. The residual nitrogen of the blood pressure varies in the scarlet fever patient as in the normal individual within fairly wide limits. In two cases the rise of the residual nitrogen preceded the appearance of nephritis, whereas other inflammatory complications had no influence on the residual nitrogen.

EPITOME OF CURRENT MEDICAL LITERATURE.

Medicine.

615. Active Immunization against Erysipelas.

K. E. BIRKHAUG (*Journ. Amer. Med. Assoc.*, March 19th, 1927, p. 885) has found that *Streptococcus erysipelatis* produces a soluble and thermostable toxin when grown in the Douglas tryptic medium digest for a period of five days, the concentration of toxin varying between 10,000 and 50,000 skin doses per cubic centimetre. During the acute stage of erysipelas the patient's skin reacts positively with the skin-test doses of *Streptococcus erysipelatis* toxin until about the tenth day of disease, when the reaction becomes rapidly negative to multiple skin-test doses of toxin. Simultaneously with the immunization of the skin to erysipelas toxin, the toxin in the patient's blood and urine completely disappears, and is replaced by a gradually increasing amount of antitoxin in the patient's blood serum, which in proper mixtures completely neutralizes the toxin produced by *Streptococcus erysipelatis*. Active immunization against erysipelas toxin, conferred by an attack of erysipelas, disappears in some persons six weeks after the onset, and their skin reactions suddenly become positive. It was found that persons with a history of recurrent attacks of erysipelas contracted the disease almost simultaneously with the reappearance of a positive skin reaction. Active immunization against recurrent attacks, by bi-weekly intramuscular injections of 500, 5,000, and 50,000 skin-test doses of the extracellular and intracellular toxin derived from *Streptococcus erysipelatis*, produced in the patient's blood serum a rapidly increasing concentration of antitoxin, so that in some persons 1 c.cm. of blood serum was able to neutralize completely 1,800 skin-test doses of toxin. Birkhaug records twenty-four cases with definite histories of frequent recurrent attacks of erysipelas; after active immunization the patients remained free from recurrent attacks for a period approaching two years.

616. Endocarditis Lenta.

A. F. CAGIGAL and C. CORTÉS (*Ars medica*, March, 1927, p. 68), who record an illustrative case in a woman, aged 23, with an account of the necropsy, state that endocarditis lenta is usually caused by *Streptococcus albus*. A history of inherited cardiac disease may often be obtained. The predilection of the lesions for the mitral valve can be explained by the fact that this valve is the most frequently affected by previous disease. In the present case the patient had suffered from acute rheumatism and typhoid fever. The condition of endocarditis lenta is characterized clinically by asthenia and septic fever. On the other hand, apart from the murmur, which remains unchanged from first to last, the cardiovascular symptoms are ill marked, and are only a terminal manifestation. The duration of the disease ranges from four to fourteen months. The fatal issue, which according to Vaquez is invariable, though Libman speaks of a recovery rate of 3 to 4 per cent., may be due to various causes, but is almost always the result of embolism. The diagnosis can only be made by repeated blood cultures. The conditions which must be excluded by the appropriate tests are tuberculosis, syphilis, pernicious anaemia, and malaria. Osteotrophic changes in the extremities, such as clubbed fingers, and ecchymoses in the skin, indicate an early death and are the result of capillary thrombosis and embolism. Treatment so far has been ineffectual.

617. Preventive Vaccination for Typhus.

SINCE the complete extermination of lice is impossible, C. NICOLLE, HÉLÈNE SPARROW, and E. CONSEIL (*Arch. de l'Inst. Pasteur de Tunis*, 1927, T. xvi, p. 1) discuss two methods for producing an immunity against typhus in those who are brought into contact with the natives of those countries where typhus prevails, and who are exposed to infection by lice. The first method, based on observations during epidemics that one attack confers a lasting immunity, consists of the inoculation of the serum of convalescent patients, or of donkeys which have recovered from typhus fever; unfortunately the serums are not invariably active. Though the immunity conferred by this method is immediate it is of short duration, often lasting only a few days; yet it is useful for medical practitioners exposed to contagion. The second method, which confers a less rapid but more lasting immunity, consists of giving an emulsion of infected guinea-pig's brains, which has a higher virulence than the serum, by subcutaneous inoculation of a series of graduated increasing doses. The authors give full details of the preparation of this emulsion, the dose of which can be roughly standardized. They recommend that the first injections should be attenuated by twenty-four hours' exposure in an ice-box, and also that each series of four to six daily injections should be separated by intervals of several weeks in order to ensure that the subject receiving a new series of more virulent injections has passed the longest period for a delayed typhus attack to declare itself. Two men on whom the test was made received three series of virulent inoculations on six, four, and four consecutive days respectively, representing for each series five, nine, and twenty-four virulent doses. The series were separated by intervals of twenty-eight days, twenty-eight days, and two and a half months; after a further two and a half months had elapsed both resisted a single inoculation of twenty virulent doses.

618. Measles and Lobar Pneumonia.

M. PAILLE (*Thèse de Paris*, 1926, No. 385) states that acute lobar pneumonia is rarely seen in measles wards. According to the cases recorded in the literature and his own experience it only occurs in convalescence. In such cases, therefore, there is a succession rather than an association of two diseases. The frequency of the post-eruptive pneumonia does not appear to be greater than can be explained by a mere coincidence. Apart from herpes facialis, which is never found, it presents all the clinical symptoms of true pneumonia. Paille records three examples of lobar pneumonia which developed in convalescence and were the only examples of this sequel among 3,000 cases of measles observed in Professor Teissier's service at the Hôpital Claude Bernard.

Surgery.

619. Fracture of the Lumbar Vertebrae.

R. H. KENNEDY (*Annals of Surgery*, April, 1927, p. 519) finds that there is considerable difference of opinion about the frequency of fractures of the transverse processes of the lumbar vertebrae. The condition, which is not uncommon, results from direct violence or muscular strain, the former being the more usual. These fractures are usually multiple, and when uncomplicated by fractures of the body, all occur on the same side. The symptoms and physical signs are those of a severe strain of the back. Pain is usually sharp when the patient attempts to turn over. There may be no deformity or swelling of the soft parts. The diagnosis can only be definitely made by an *x*-ray examination. The resulting disability is due solely to the associated strain of the back, and the fracture is negligible. Owing to the frequency of traumatic neurosis it is wiser to keep the knowledge of the fracture from the patient. Bony union is definite in a number of these cases. The treatment is rest in bed with massage and radiant heat. Prolonged immobilization is not necessary. Patients were found fit and able to walk in an average of sixteen days after the injury. Disability of over six months is unusual. The majority should return to work within two months with no complaints referable to the injury.

620. Treatment of Fracture of the Neck of the Femur.

C. E. JANCKE (*Zentralbl. f. Chir.*, March 26th, 1927, p. 790) describes the results obtained by various methods of treatment of fracture of the neck of the femur. In fifteen cases treated with strapping extension, abduction, and internal rotation, and about four months in bed, satisfactory results (including functionally efficient pseudo-arthroses) were recorded in 66 per cent. Recent investigations have shown that extensive regeneration of bone may occur even in elderly patients, commencing in the upper fragment after temporary necrosis; this should, therefore, not be removed, but bony union by accurate alignment of the fragments aimed at. Nine patients, with an average age of 66, were treated by Basset's method, in which apposition of the fragments is first obtained and the centre of the head accurately marked on the skin surface under *x* rays; a screw is then introduced with specially devised instruments and the patient allowed to get up comparatively early. Several deaths occurred during the treatment, and the only case which showed a satisfactory functional result after three years and nine months was a trochanteric fracture in a woman aged 75, in which the position of the fragments immediately after the injury was such that any conservative method of treatment would probably have yielded a satisfactory result. This procedure has

therefore been abandoned by the author in favour of Whitman's method of keeping the patient recumbent, with the limb abducted and internally rotated in plaster for three months. The patient is then allowed to get about for one month on a patten before the foot is taken out of plaster; after another month the plaster is removed from the knee, and after six months' treatment the plaster is entirely discarded, the patient continuing to wear a calliper for a further six to twelve months. Nine cases of a total of seventeen were treated more than one year previously, and among these two deaths were recorded (delirium tremens and senile marasmus) and two resulted in non-union (one tabetic and one epileptic); the remaining five showed good functional results. Recently, since Kreutz and Mau have shown that the radiogram may be deceptive and the fragments tend to separate again with extreme internal rotation, moderate internal rotation only has been applied. Jancke found that elderly patients stood the prolonged plaster treatment remarkably well, and, as a result of his own observations and those reported by others, considers this the method of choice.

621. Treatment of Arterio-venous Aneurysm.

P. MOURE (*Bull. et Mém. Soc. Nat. de Chir.*, April 2nd, 1927, p. 463) discusses a case, reported by M. Picard, of a popliteal arterio-venous aneurysm arising in a miner as the result of an injury. The aneurysm was treated by resection of the vein and lateral suture of the artery, which Moure considers the ideal treatment whereby the continuity of the arterial trunk is restored. The operation in the case described was successful, and the functional result perfect. Moure states that arterio-venous aneurysms as a general rule give good results after surgical treatment, probably owing to the development of the collateral circulation and the absence of clots in the sac. In simple arterial aneurysms these clots are a source of danger since, during the operative manipulations, they may be set free and block the peripheral vessels, leading to gangrene of the affected limb. Arterio-venous aneurysms may also be treated by quadruple ligature of the vessels and extirpation of the sac. The best operation is, however, one which re-establishes the continuity of the artery. In this operation the simplest method is to incise the sac or the dilated vein longitudinally, after producing haemostasis with a tourniquet. It is then easy to recognize the opening into the artery, the edges of which are always thick and well defined; the opening is easily closed by lateral sutures. This operation is found to give most satisfactory results. During it the limb must be completely exsanguinated so that the aneurysmal sac may be freely opened and the orifices of the vessels be examined where they open into it. In this way the suturing can be performed without difficulty or interference from the oozing of blood.

622. Internal Gall-bladder Drainage.

W. A. STEEL (*Surg., Gynecol. and Obstet.*, March, 1927, p. 393) advocates internal drainage of the gall bladder (cholecystoduodenostomy or cholecystogastrostomy) as a routine operative procedure, and reports the results of 100 such operations performed between four and eight years ago under spinal stovaine anaesthesia with drainage for two days. The gall bladder, exposed by an upper right rectus incision, was freed from its liver attachment sufficiently to allow the fundus to lie against the point of anastomosis without tension or kinking. An end-to-side anastomosis with the duodenum or stomach was performed, using linen thread for the serous stitch and No. 00 chromic gut for the through-and-through buttonhole stitch; a cigarette drain was carried to the seat of anastomosis and removed within forty-eight hours. Cholecystoduodenostomy was performed in 54 cases and cholecystogastrostomy in 46. The operative mortality was *nil*, and the post-operative 2 per cent., one patient dying from epidemic influenza and the other from hypostatic pneumonia. Steel states that acute or subacute pancreatitis is a contraindication for internal drainage because of the possibility of digestion of the tissues surrounding the seat of anastomosis. The youngest patient was 18 and the oldest 72, the average age being 41; 92 were females and 8 were males. In five cases in which exploratory reopening of the abdomen was required within from eight months to five and a half years after the primary operation the adhesions were found to be slight and not comparable with the dense scar tissue found after cholecystectomy. The gall bladder had the appearance of a round tube about 3/8 inch in diameter. It resembled the intestine rather than the normal gall bladder; it remained patent as an accessory bile duct and served to resist infection from the bowel, so that there was no danger of an ascending liver infection. Steel concludes that the procedure has a lower mortality and affords less liability to cholecystitis than cholecystectomy. It accomplishes the same purpose while it eliminates common duct surgery, and therefore is the operation of choice in infected gall-bladder cases.

Therapeutics.

623. Treatment of Severe Anaemias with Liver.

W. AITOFF and G. LOEWY (*Presse Méd.*, April 30th, 1927, p. 545) discuss the treatment of severe cases of anaemia by the administration of liver as described by Whipple in 1920. Two cases treated in this way are reported. The first patient, a woman who had probably a grave pernicious anaemia, steadily became worse after prolonged treatment by intravenous and subcutaneous injections of citrated blood and of arsenic; liver was then tried. The patient was at first too ill to digest it, so the liver was pounded, strained, and given, in the water in which it had been boiled, by means of a tube as a viscous broth. No drug treatment for the anaemia was continued. In sixty-five days the red corpuscles rose from 1,560,000 per c.mm. to 4,420,000 and the haemoglobin from 27 to 66 per cent. Before taking liver the condition of the patient was serious, and hope had been almost abandoned, but the weight increased, the appetite returned, she slept well, and was able to go for walks. The second patient was a woman with severe anaemia following malaria. Drugs had been tried in vain and were stopped when the liver treatment was begun. The liver was prepared in a similar way but was taken normally by the mouth. In seven weeks the haemoglobin rose from 32 to 60 per cent. and the red corpuscles from 1.5 to 3.5 million. The improvement was dramatic as regards weight, sleep, appetite, and the general condition. The authors emphasize the importance of preparing the liver correctly. It was boiled for ten minutes in water just sufficient to cover it, then it was pounded and strained through three sieves, the last of which had a very fine mesh. The sieves were washed through with the boiled water to which was then added the fine particles of liver. Rather more than half a pound was given daily. Grilled, roasted, or seasoned liver was found to have no effect, but probably it could with advantage be given raw, chopped up, passed through a sieve, and taken in a vegetable or meat soup.

624. W. P. MURPHY, R. T. MONROE, and R. FITZ (*Journ. Amer. Med. Assoc.*, April 16th, 1927, p. 1211) report the successful treatment of ten patients with pernicious anaemia by a diet rich in cooked calves' or beef liver. Careful examination of the blood pictures indicated that this diet appeared to cause the appearance in the general circulation of new young red blood cells; there was evident also a marked reaction in the bone marrow with a decrease of bile pigment in the serum. No change was detected in the non-protein nitrogen of the plasma or in the plasma protein, though the corpuscular protein was much increased. The treatment lasted in most cases for several months and the only drug employed was dilute hydrochloric acid.

625. Treatment of Malaria by Plasmochin.

A. DUBOIS (*Bruxelles-Médical*, April 17th, 1927, p. 785), in a review of the progress of tropical medicine during 1926, discusses the treatment of malaria by plasmochin, which is a synthetic derivative of quinoline. It has been shown to be active in tertian and quartan malaria, but is less effective in tropical malaria, where it is therefore combined with quinine. It has, however, a gameticide action of great importance in prophylaxis. The dose is 0.02 gram repeated three to five times daily. A daily dose of 0.1 gram occasionally causes slight cyanosis, methaemoglobinuria, and gastric disturbance. Patients in whom quinine produces haemoglobinuria are found to tolerate plasmochin. Dubois states that the treatment should be continued for not more than five days; it may be resumed after an interval of four days, and continued with alternative periods of treatment and rest. Relapses are said to be less frequent than after quinine, and yield to further treatment by plasmochin. Dubois adds that its prophylactic utility deserves careful study.

626. Thallium Acetate in Fungus Infections.

H. KLEINMANN (*Dermatol. Woch.*, April 9th, 1927, p. 493) treated 114 cases of fungus infections of the scalp, including 38 cases of favus, with thallium acetate, and obtained very satisfactory results in 108 cases. The patients' ages ranged from 6 months to 16 years. One dose of 7 mg. per kilogram of body weight was administered to patients weighing more than 25 kilograms, the others receiving 8 mg. Total epilation generally occurred in fourteen to nineteen days; the hair began to grow again in four weeks and returned to normal in another two months. The author agrees with Urnena in ascribing the prolongation of the latent period, recorded in later cases treated, to deterioration ("fatigue" phenomena) of the thallium salt, no undesirable effects being, however, observed. Among the patients were 21 in whom patchy and incomplete epilation

had previously been produced by inadequate *x*-ray treatment; thallium acetate was administered to these, four to five months subsequently, when the hair had grown again, and the epilation results were as satisfactory as in those patients who had not been subjected to *x* rays previously. In half the cases treated the hair along the frontal margin remained unaffected, and in 17 the lateral half of the eyebrows fell out. This suggests that the frontal part of the scalp and the medial part of the eyebrows are not included in the sympathetic innervation of the rest of the scalp, and supports the hypothesis that the thallium acts through the endocrine vegetative system. Blood examinations showed lymphocytosis and eosinophilia appearing two weeks after the administration and disappearing three weeks later; temporary achlorhydria was also frequently observed. In four patients folliculitis of the scalp occurred, but soon subsided again. No urinary changes or other ill effects were detected.

Radiology.

627. **Treatment of Naevi with Radium.**

ZOE A. JOHNSTON (*Radiology*, April, 1927, p. 292) advocates the treatment of naevi with radium as affording the most thorough removal with the best cosmetic result, a large number of cases having been uniformly successful. The advantages claimed are painlessness, ease of application, absence of marked reaction and of effect on the surrounding healthy tissue, while leaving a minimum of scarring with no contracture of the skin. The disadvantages are that the treatment is slow and expensive, while telangiectasis may appear later. In dealing with port-wine marks the method recommended is to make the application to the entire mark with at least two months' interval between treatments, but should the lesion be so large as to render an entire application impossible at a sitting it should be treated in sections. Vascular naevi elevated above the skin and involving only the superficial vessels respond readily to radium, one or two applications sufficing for small lesions, though larger ones will require more. If they are definitely elevated above the skin surface, radium needles can be inserted with advantage, one such treatment taking the place of several surface applications and so considerably shortening the length of treatment. Angioma cavernosum responds to radium treatment better than to any other method, beta radiation being indicated if the growth is not too deep, and gamma rays, or burying radium in the mass, if extensive. When there is a normal skin surface the condition is very suitable for embedded radium. The author insists that treatment should commence as soon as it is safe to take the babies out of the house.

628. **Nephritis following X-ray Treatment.**

G. DOMAGK (*Med. Klinik*, March 11th, 1927, p. 345) suspected that the chronic glomerular nephritis found in some children who had died from abdominal tuberculosis was associated with the repeated *x*-ray treatment they had received some months before death. He found that in rabbits killed over a year after radiation the weight of the treated kidney was only about a tenth of the weight of the untreated hypertrophied compensating kidney. By observations of many rabbit kidneys it was shown that the chief changes occurred in the tubular epithelium, these being soon followed by round-cell infiltration of the interstitial tissue. In some cases a few days after [illegible] on were seen in the cortex. [illegible] cicatricial tissue were found [illegible] still quite healthy glomeruli. In many of these contracted kidneys the tubules were completely destroyed. There was no support of the original suggestion that the glomerular affection was dominant, or that the contracted kidney following roentgen radiation was caused by glomerular nephritis. The author considers that in some cases an acute glomerular nephritis can result from radiation, and that radiation can aggravate an already existing nephritis.

629. **Iodized Oil in Bronchography.**

J. J. SINGER (*Archives of Surgery*, January, 1927, Pt. II, p. 167) has used for mapping the lung lipiodol and iodipin, each of which contains 40 per cent. by weight of iodine. He mentions five methods of introducing the oil: (1) through a trocar needle into the trachea; (2) under direct laryngoscopic examination; (3) through the bronchoscope directly into the lung; (4) through a tracheal catheter; (5) by injection into the pharynx of 20 c.cm. of oil while the patient extrudes his tongue as far as possible. From 20 to 40 c.cm. of the oil must be introduced in order to produce suitable radiograms. Singer has employed the fifth method with excellent results and little discomfort to the patient. He states that most of the oil will be coughed up within fifteen to twenty minutes, but the remaining opacities persist for some months. The first method is recommended for children, the fourth and fifth for adults, and the second and third when bronchoscopy is performed for other purposes. Singer states that the oil can be used to map out chronic empyemic and bronchial fistulas, and in pneumothorax and bronchiectasis shows well the collapsed bronchi. He maintains that bronchography with careful physical examination is of great value, displaying excellently the bronchial tree with abnormalities present. It is said to be harmless if properly used, but should not be employed when simpler methods are possible. G. TUCKER (ibid., p. 175) states that the introduction of the oil by the bronchoscope is safer and more accurate than by blind methods; that bismuth subcarbonate insufflation gives the clearest results in outlining the trachea and larger bronchi, and in bronchiectatic dilatation, and that the oil is best in abscess cavities and the periphery of the lung. E. W. ARCHIBALD (ibid., p. 206) maintains that in tuberculous cases iodized oil should be used with caution. He finds its injection useful in old thoracoplasty cases, and in the progress of a several-stage operation for bronchiectasis or abscess of the lung.

630. **Radiological Treatment of Epithelíomata.**

H. BEAU (*Paris Méd.*, April 16th, 1927, p. 383) refers to the well known fact that when a malignant growth has been treated by *x* rays or by radium, and complete sterilization has not been obtained, the radio-sensitivity of the growth is diminished. With subsequent treatment the radio-resistance is increased and the surrounding tissues become still more sensitive, and finally the cancer becomes incurable by radiation, except when massive necrotic doses are employed. He has reported 77 per cent. of successes obtained in 344 patients with cutaneous epithelioma who had not received any radio treatment previously, but of 75 patients who previously had received one or more radio applications, cure occurred in only 40 per cent. Of the 344 cases 280 received only one application, and cure resulted in 87 per cent. If one or more failures necessitated repetition of the treatment the results were not so good; of 18 cases irradiated for the third time after a second relapse only 11 per cent. were successful. It was noted that on the second and third radiation a much stronger dose was administered, which seems to support the view of an acquired radio-resistance by the growth. Of 80 cases of cutaneous epithelioma which had relapsed after treatment by *x* rays 9 were again treated with *x* rays, but with success in only 22 per cent.; the remaining 72 patients were treated with radium, there being 43 per cent. successful results. In 58 cases of relapse after treatment with radium only 20 per cent. were cured by *x* rays, whereas 53 other patients treated with radium gave 38 per cent. successes. Beau concludes that it is better to treat relapses with radium than with *x* rays.

Obstetrics and Gynaecology.

631. **After-History of Eclamptic Patients.**

H. NEVERMANN (*Arch. f. Gynäk.*, January 31st, 1927, p. 891), from the careful investigation of sixty patients who had suffered from eclampsia from one to twenty-three years previously, concludes that inconvenient, though not disabling sequels, are not uncommon. Thirteen patients reported severe headache and twelve complained of poor memory. Nevermann thinks that these are to be correlated with the minute haemorrhages and thromboses which are found microscopically in the brain during eclampsia, and with the bushy neuroglial proliferations which are found to replace the Purkinje cells and their dendrites in patients dying of intercurrent disease shortly after an attack of eclampsia. Four patients had visual defects, and five some swelling of the legs. Eight women had high blood pressure (140 to 170 mm.). Three only had albumin and cylindrical casts in the urine, but, of these, two were cases of recurrent pregnancy toxaemia and one an instance of very slight albuminuria within one year after an eclamptic illness; no transition from eclampsia to chronic nephritis was demonstrated in the present series. It is admitted that albuminuria and the presence of casts are frequently to be found for some time after eclampsia and that a necropsy at this stage shows morbid tubal though no glomerular changes, but the albuminuria and casts tend to diminish and disappear in course of time, and erythrocytes, even in small numbers, are never found, which is in marked contrast with chronic nephritis. The sixty women examined were the only traceable ones of a series of nearly three hundred.

632. Foetal Hydronephrosis as a Cause of Dystocia.

F. VOZZA (*Ann. di Ostet. e Ginecol.*, February 28th, 1927, p. 87) has found records of about 110 cases of dystocia following obstructive conditions in the foetal urinary tract, morbid urethral being more common than morbid ureteral findings. He records the case of a woman, aged 39, in whose eighth pregnancy labour at term, with a foot presentation, advanced slowly in spite of severe pain. The foetus died during labour. Podalic extraction was found to be impossible, and 750 c.cm. of fluid were withdrawn by puncture of the foetal abdomen. Labour, nevertheless, was still obstructed by a cystic fluctuating swelling; further puncture led to escape from a hydronephrotic sac of 1,500 c.cm. of clear fluid, and spontaneous delivery followed. The male foetus weighed nearly 6 lb., the distal part of the spongy urethra was impervious, and the whole of the suprajacent portions of the urinary tract were dilated. Hydronephrosis was present to a moderate extent on the right, and on the left had been so extreme as to cause dystocia. The obstruction in the urethra consisted solely in a non-inflammatory hypertrophy of the folds of the mucous membrane.

633. Pyelography and Pyelo-nephritis of Pregnancy.

LEVY-SOLAL, MISRACHI, and SOLOMON (*Journ. de Radiol. et d'Electrol.*, March, 1927, p. 170) have investigated by pyelography the occurrence of pyelo-ureteral anomalies in connexion with the difficulties so frequently encountered in the course of routine catheterization employed in the treatment of pyelo-nephritis in pregnancy and the puerperium. The authors refer to the classic theory of ureteral compression, or rather elongation, and the possibility of a right ureteral kink being produced by the ascent of the pregnant uterus; they conclude that renal infections are due to stasis in the intestine and renal pelvis, the latter being aggravated by anatomical predisposition. They have observed three cases, using lipiodol as the pyelographic medium, since it is well tolerated, antiseptic, and opaque. The patients' confinements were normal, and two were seen fifteen days and twenty-five days respectively after delivery. The former patient, aged 38, required a nephrostomy before her condition began to improve. The second patient, who was sent to hospital for persistent fever and general ill health, was confined the next day spontaneously. Subsequently she had much pus in the urine and she did not improve until nephrostomy was performed. The third patient was cured by bilateral ureteral catheterization without nephrostomy.

634. Bilirubinaemia and Ectopic Pregnancy.

C. TENCONI (*Ann. di Ostet. e Ginecol.*, March 31st, 1927, p. 127) has estimated by the van den Bergh indirect method the percentage of bilirubin in the serum of 68 patients suffering from various gynaecological disorders, comparing it with that of 28 patients who had recently had intraperitoneal haemorrhage following rupture or abortion of ectopic tubal gestation. In common with other observers he has found a physiological bilirubinaemia in about 50 per cent. of persons with healthy circulatory and digestive systems. In the case of ectopic pregnancy with haemorrhage the bilirubin of the blood serum was by no means always increased and frequently within physiological limits; in about 25 per cent. the test was negative. He concludes, therefore, that examination of the serum for bilirubin is of little value in the differential diagnosis of ruptured tubal gestation. Fairly well marked haematogenous icterus has been described in numerous cases of pelvic haematocele, and he author reports another instance of this.

Pathology.

635. The Influence of Sodium and Calcium Salts on Glycaemia.

M. LABBÉ, F. NEPVEUX, and ROHACEK (*C. R. Soc. de Biologie*, May 6th, 1927, p. 1145) state that mineral salts act on the intra-organic metabolism, not by their molecules, but by their more or less dissociated ions; and Loeb has shown that calcium ions lessen or neutralize the action of potassium ions. The present authors have studied the evolution of glycaemia in both normal and diabetic subjects after the administration of certain salts of sodium and calcium, the blood sugar being estimated by Bang's method. Sodium lactate in large doses caused an immediate hyperglycaemia in both normal and diabetic cases. Sodium bicarbonate in large doses produced a tardy and slight hyperglycaemia, and the intravenous injection of a smaller dose of the same salt was accompanied by a marked hyperglycaemia in both classes of subjects. The administration of calcium lactate caused a glycaemic lowering, but while the hypoglycaemia was prolonged in diabetics, it was followed in normal subjects by a very slight hyperglycaemia. The authors find that the action of the salts of calcium and sodium is complex. The ion Na associated with the acid radicals, CO_3H, and lactic acid raises the glycaemia in all subjects, while associated with PO_4 it does not. In diabetics, if mono- and bimetallic phosphates are administered with glucose, a weaker hyperglycaemic reaction follows than with glucose alone. Seemingly, the preponderating action is due to the anion PO_4 rather than to the cation Na. Calcium lactate and chloride produce in diabetics a hypoglycaemia, which results from the action of the cation Ca rather than from chlorine or lactic acid. The biochemical action of these salts on glyco-regulation is unknown, and may be explained by one of three hypotheses: (1) in diabetics sodium salts diminish, while calcium salts favour, the accumulation of glycogen in the liver and tissues; (2) these salts act directly on the nerve centres controlling glyco-regulation; (3) a specific action of the salts on the insulinic hormone. The authors add that whatever the explanation may be experience has shown the hypoglycaemic action of calcium salts, and consequently their possible use in the treatment of diabetes by lessening carbohydrate metabolism.

636. Diagnosis of Brucella abortus and Brucella melitensis.

E. VALENTI (*Biochimica e Terapia Sperimentale*, March 31st, 1927, p. 77) has carried out a series of tests to enable him to distinguish between *Brucella melitensis* and *Brucella abortus* Bang. He found that if saline suspensions of agar cultures were heated to 100° C. for one hour many of the *melitensis* strains spontaneously agglutinated, while strains of Bang's bacillus never did so. Of forty-four *melitensis* strains tested twenty showed flocculation within the hour. By this means it is possible to divide the strains of *melitensis* into two groups; one group behaves like the *abortus* strains, the other group undergoes spontaneous agglutination. The next test he used was direct agglutination, using antigens that had been deprived of their lipoids. Cultures on agar, forty-eight hours old, were suspended in 12 to 14 c.cm. of saline and heated to 100° C. for an hour. This treatment caused a number of the *melitensis* strains to auto-agglutinate. The remaining strains, which remained clear, were allowed to cool, mixed with an equal quantity of sulphuric ether, shaken, and allowed to stand till the ether had separated out on top. The underlying fluid was then withdrawn and heated to 55° to 60° C. for twenty minutes to drive off any traces of ether that might be left; they were then used as antigens in the usual agglutination test. The immune serums that were chosen came either from naturally infected persons and animals or from artificially immunized rabbits. The mixtures of serum and antigen were incubated for three and a half hours at 60° C., and were then left at room temperature for about twenty hours. Readings were taken at three or four different times. Using untreated antigens he found that strains both of *abortus* and of *melitensis* were agglutinated by both anti-*abortus* and anti-*melitensis* serums. But when the antigens used had been deprived of their lipoids he found that while both organisms were agglutinated by an anti-*melitensis* serum, only the *abortus* strains were agglutinated by an anti-*abortus* serum. In other words, removal of the lipoids had rendered the *melitensis* strains inagglutinable by anti-*abortus* serum. This test, he considers, affords a method of distinguishing the two organisms. When he employed it on a number of American strains he found that all strains coming from human patients reacted as *melitensis*, even though in America some had been diagnosed as *abortus*.

637. Physico-Chemical Properties of Exudates and Transudates.

G. MELLI (*Rif. Med.*, March 21st, 1927, p. 269) corrects the generally accepted statement that there is an equal concentration of crystalloids in the blood and in the effusions. By estimating the freezing points of the liquids he finds that the cryoscopic value Δ is 0.55 to 0.56 for blood and 0.52 to 0.55 for the exudates and transudates, and concludes, therefore, that the blood has a slightly higher crystalloid content than the exudates and transudates. There is an almost identical difference in the value Δ between the ultrafiltrated blood and the ultrafiltrated effusions. Sodium, potassium, and chlorine are present in practically the same concentration in the blood, the exudates, and the transudates. The sugar content of the exudates is the same or slightly higher than that of the blood, and markedly higher in the transudates. The calcium content is higher in the blood than in the exudates and slightly higher in the transudates than in the exudates. The amount of non-diffusible calcium seems to be greater in the serum than in the effusions, and more in the exudates than in the transudates. The addition of a calcium salt to an albuminous solution induces a permanent increase of osmotic pressure in the same solution, which is verified, or only temporarily verified, by the addition of some other salt such as a salt of sodium.

EPITOME OF CURRENT MEDICAL LITERATURE.

Medicine.

638. Typhoid Infection of the Joints.

H. SCHAEFFER and R. LIÉGE (*Paris Méd.*, April 9th, 1927, p. 346) state that though joint symptoms are not common in typhoid fever they are not extremely rare, as Grenet and Fortineau noted them in 7 out of 236 cases. Three principal forms may be described. The first constitutes the arthralgic form of Bazin and Potain, which is characterized merely by transient pains in the joints. The second form consists of suppurative arthritis involving several joints, more frequently a single joint, especially the hip, ending in ankylosis or spontaneous dislocation. The third form consists of serous polyarthritis resembling acute articular rheumatism. As a rule these joint manifestations do not occur until the beginning of defervescence, but in very exceptional cases they constitute the first sign of typhoid septicæmia, so as to merit the title of arthrotyphoid suggested by Robin and Leredde. The present authors have collected nine cases of arthrotyphoid, including the following personal case. The patient was a man, aged 46, whose principal symptoms for the first fortnight of the disease were fever and pains in the joints, which were attributed to acute articular rheumatism, although they were not relieved by sodium salicylate. Some of the joints were merely painful and others were red and swollen. It was only between the fifteenth and twenty-first day that the symptoms of typhoid fever, including parotitis, developed and the Widal reaction was found to be positive; recovery followed. As three of the nine cases of arthrotyphoid were fatal, the prognosis is grave. Although the examination of the serous fluid was negative in the only case (that of Danlos and Straus) in which it was made, it is reasonable to suppose that the articular localization is due to typhoid or paratyphoid bacilli. In most cases the cause of the localization is obscure, though in one instance there was a recent trauma and in another a previous attack of acute articular rheumatism.

639. The Prophylaxis of Scarlet Fever.

J. A. TOOMEY, R. M. FULLERTON, and M. E. KISHMAN (*Amer. Journ. Dis. Child.*, March, 1927, p. 420) report the result of their attempts to establish active or passive immunity in the personnel in the contagious disease department of the Cleveland City Hospital. Active immunity was established in 632 out of 649 cases after three injections, the Dick test becoming negative in from eight to thirty-five days after the last injection; in eight a fourth injection was required, in three a second series of three injections, while in four the reaction remained positive after three complete series of injections. Out of twenty cases actively immunized, nineteen did not contract scarlet fever when subsequently exposed to infection, but in the twentieth case a fleeting erythema appeared and was diagnosed as a doubtful scarlet fever; on the other hand, thirty-five unimmunized persons all contracted the disease while working in the scarlet fever ward. The authors state that individuals with negative Dick reactions generally have negative reactions for at least eighteen months. An initial immunizing dose of 250 skin-test doses is recommended; larger doses may produce a severe local reaction or even scarlet fever in susceptible persons. The authors admit failure in their attempts at passive immunization with scarlet fever antitoxin; not only was no protection against the disease obtained, but the serum sickness that often followed, in spite of concentrated antitoxin being used, was much more severe than the disease itself.

640. Pneumococcal Peritonitis.

M. BERGAMINI (*La Pediatria*, April 15th, 1927, p. 401) reports four cases of pneumococcal peritonitis in girls. He believes that the family history as a rule has no special influence on this condition. In two of his cases the onset was slow; one patient suffered from worms, another from repeated attacks of gastro-enteritis, and in one case trauma seemed to play a part. In two cases the pneumococcus was recovered from the blood, and the author thinks that the organism is more likely to be conveyed by the blood than by the lymph. There was no evidence of infection through the genitalia. Coryza was present in two cases and herpes in three. Pneumococcal peritonitis is stated to be more often primary than secondary in origin; it usually sets in suddenly. Relapses are not uncommon, and some of the attacks may be so slight as to suggest an abortive infection. Pain, generally very acute, is common; vomiting is usually present, the stools are loose, and the temperature is high. At first the abdomen is tympanitic, but later local areas of dullness appear; towards the later phases the abdomen becomes globose, with bulging of the umbilicus and possibly some discharge of pus. There is marked wasting and the peritonitic facies is present. The urine is diminished and contains excess of carbonates, phosphates, and traces of albumin. Tubercle may coexist and cause a positive von Pirquet reaction. In the differential diagnosis tuberculosis, streptococcal peritonitis, appendicitis, and typhoid fever have to be considered. In tuberculous peritonitis a change of position more readily alters the level of the fluid dullness than in pneumococcal infection, and in the former condition the intestinal coils come up against the anterior abdominal wall. In pneumococcal peritonitis the umbilical cicatrix is flattened and red, and the onset is much more abrupt. Tuberculous peritonitis affects children under the age of 5, while pneumococcal peritonitis is more common over this age, and in females than in males; ascites occurs often in the tuberculous type. Intestinal perforation due to worms does not set up peritonitis except in intestines already softened and damaged by disease. Owing to the tendency to encystment in the pneumococcal form it is not advisable to operate very early. The prognosis in the generalized form is grave.

641. Vagus Spasm.

V. MIKULOWSKI (*Monatsschr. f. Kinderheilk.*, April, 1927, p. 303) describes a case of vagus spasm in a boy aged 13. These cases, characterized by persistent, almost daily, attacks of abdominal pain and vomiting, were regarded by Rejchmann, by whom they were first described, as a gastric neurosis. Recently, however, the existence of an internal secretion, originating in the liver, or possibly the kidneys, and antagonistic in its action to the adrenal secretion, has been postulated; if this anti-adrenaline were present in excess, as Mikulowski believes to have been the case with his patient, the sympathetic system would be weakened in action, the blood pressure would be low, the vagus would be hyperactive, and there would probably be evidence of hypertonus of the other cranial or spinal vessels. The salient features of Mikulowski's case were: (1) Persistent intractable daily attacks of abdominal pain and vomiting during six years, unrelieved by any treatment. (2) Brown pigmentation of the skin and limbs. (3) Nervous instability of a tetanic type—Chvostek's and Trousseau's signs positive; during the attacks convulsions of a tetanic character were found in arms, hands, legs, and feet, and occasionally the whole body assumed the opisthotonic position. (4) The blood pressure was 65 to 60 mm. and the pulse 60. The boy was given adrenaline, with instantaneous effect on the blood pressure and pulse rate; the convulsions ceased and the vomiting grew gradually less and finally ceased. Thyroid tablets were then substituted for the adrenaline and the patient continued to improve, nor, six months later, in spite of all treatment having been discontinued, has there been any recurrence.

642. Asthma caused by Allergic Skin Tests.

J. W. SAMSON (*Med. Klinik*, April 8th, 1927, p. 506) reports a case of the accidental production of a severe attack of "experimental" bronchial asthma in a hay fever patient who had never previously suffered from asthma or urticaria; the case also demonstrates the close relation between the various allergic phenomena, asthma, urticaria, and hay fever. A girl, aged 18, had suffered from "hay fever" during the spring and summer months for six or seven years. The cutaneous reactions to a control of decinormal sodium hydrate and to powdered animal and vegetable protein being negative the patient's sensitiveness to cutaneous and intracutaneous applications of minimal doses of fluid extracts of five different kinds of grasses was tried. In ten to twenty minutes wheals appeared at the sites of the injections, except of the control, and gradually increased in diameter up to two to three inches; general symptoms of extreme respiratory embarrassment, with expiratory stridor, dyspnœa, swelling of the nasal mucous membrane, and small rapid pulse, gradually developed. This was followed by nausea, vomiting, and generalized urticaria with severe irritation which lasted about three and a half hours. An injection of adrenaline at the onset of the dyspnœa and pulse acceleration produced severe localized pain and a sharply defined area of cutaneous anæmia lasting three hours. Five hours after the commencement the respiratory symptoms had entirely disappeared and the cutaneous were scarcely perceptible. The

blood picture before and during the attack was normal. Samson considers that ordinarily in this patient the local sensitiveness of the conjunctiva and the mucous membrane of the upper respiratory tract acted as a barrier protecting the rest of the body from the allergen specific plant proteins, and thus prevented a general or local reaction in other organs. During the cutaneous sensitivity tests this barrier was evaded and the allergens acted directly on hypersensitive cells and organs.

643. Swine Erysipelas in Man.

C. SCHAAP (*Nederl. Tijdschr. v. Geneesk.*, March 19th, 1927, p. 1447) states that swine erysipelas due to *B. rhusiopathiae suis* is a rare disease in man. It is, however, not so uncommon as is generally supposed, as he has seen three cases during the last two years. It is naturally most frequent in veterinary surgeons, butchers, farmers, and others who are brought most in contact with pigs. As a rule it runs a mild course, but occasionally fatal cases occur. The symptoms consist in a bluish-red swelling of the hands, accompanied by burning, itching, and pain. There is more or less rise of temperature and constitutional disturbance. Treatment includes local applications, such as tincture of iodine, ichthyol ointment, or compresses of Burow's solution, and the use of a specific serum. All Schaap's patients, who developed the disease after slaughtering pigs, recovered within forty-eight hours of injection of serum. He adds that usually a single dose of 20 c.cm. is sufficient.

644. Acute Polymyositis.

R. PÉROT (*Thèse de Paris*, 1926, No. 471), who records seven illustrative cases, one of which is original, in patients aged from 9 to 70, states that little is known as to the pathogenesis and etiology of polymyositis. The disease may occur at any age. The influence of sex is unimportant, but the disease appears to be commoner in males, probably because their muscular system is more active. Some writers, especially in Germany, regard acute polymyositis as an infectious disease similar to acute articular rheumatism. Two principal forms are described—namely, dermatomyositis and neuromyositis, according as the inflammation principally affects the skin or the nerve trunks in addition to the muscles. Haemorrhagic polymyositis characterized by the appearance of haemorrhages in the skin is a much rarer form. The duration ranges from a few weeks to two years, but it is more frequently fatal than the other two forms, as it is liable to be complicated by myocarditis and severe intestinal haemorrhage or nephritis. Polymyositis must be distinguished from osteomyelitis, tumours of muscles, intramuscular haematuria, gummata, hydatid cysts, and trichinosis. Treatment is the same as that of any infectious disease; balneotherapy, injections of electrargol, applications of cold compresses, and, in severe cases, fixation abscesses may be employed. When the nature of the infection has been determined by blood cultures specific treatment by vaccines or serum is indicated.

Surgery.

645. Vasectomy in Prostatic Enlargement.

A. HENRICHSEN (*Deut. Zeit. f. Chir.*, March, 1927, p. 278) discusses the treatment of the comparatively large group of patients with enlarged prostate in whom a radical operation is contraindicated because of the general condition of the patient or because of deficient renal function which does not improve with suprapubic drainage or regular catheterization. Haberer practised vasectomy in 1912 as a preliminary to prostatectomy in order to prevent the epididymitis which occasionally followed continous catheterization. He found that in 40 per cent. of his cases the original symptoms subsided to such an extent that radical operation was no longer necessary. Other workers have since confirmed these results. Henrichsen now reports four cases in which radical prostatectomy was absolutely contraindicated on account of renal inefficiency; as the only alternative was a catheter life, he exposed the vas through a short incision into the scrotum under local anaesthesia and excised a portion 1 cm. long between ligatures. In each case the prostate diminished in size and the bladder symptoms improved considerably; one patient, aged 72, who had previously been too weak to leave his bed for weeks, gained 12 lb. in weight, showed marked improvement in his general condition, and was able to work again subsequently. Henrichsen suggests that the general rejuvenescence and increased working power which follows Steinach's operation can be adequately explained along the same lines by the removal of chronic urinary intoxication from partial retention, since the impotence of the patient remains unaffected.

643. Fibroma of the Stomach.

M. SCHARAPO (*Zentralbl. f. Chir.*, April 30th, 1927, p. 1109) reports a case of the rare condition of fibroma of the stomach, and states that only five or six cases of benign gastric tumours have been recorded. A healthy woman, aged 24, after three months of indefinite abdominal pain and increasing obesity, detected a hard and smooth painless swelling in the left epigastric region. The tumour was hemispherical and as large as a child's head; the lower pole was palpable; it extended towards the right to the middle line, upwards to the epigastrium, and downwards to the umbilicus and the left flank. The genitalia were normal. A provisional diagnosis of splenic tumour was made. The patient was sent home to wean her infant, and on readmission to hospital the tumour was found to be much larger. It was most prominent below the umbilicus, and lay obliquely between the left hypochondrium and the right iliac fossa, its lower border extending to the pubic symphysis. It was dull on percussion; above it the stomach gave a tympanitic note. The tumour was quite painless, smooth, and slightly mobile. There was increasing weakness and a sense of weight in the abdomen. At a laparotomy a pedunculated tumour weighing 12 lb. was found to arise from the region of the greater curvature and the colico-gastro-splenic ligament; it was removed and the stomach wall was sutured in three layers. The growth was found to be an enormous fibroma in a very oedematous condition. In the centre of the anterior surface there was a gastric diverticulum lined with normal mucosa. Scharapo comments on the rapidity of enlargement in this case; at the patient's confinement, two months before her first admission to hospital, there was no sign of the tumour.

647. Regeneration of the Bladder.

F. DE GIRONCOLI (*Arch. Ital. di Urol.*, March, 1927, p. 325), who reports an illustrative case, remarks that cases of regeneration of the bladder after almost complete extirpation of the organ are very rare, as only eight cases have hitherto been recorded—namely, two by Nicolich, one by Velhaminoff, one by Legueu, one by Carraro, two by Delfino, and one by Ravasini. De Gironcoli's patient was a man aged 68, who was admitted to hospital for vesical tenesmus, pollakiuria, and haematuria. Cystoscopic examination showed that the whole of the mucous membrane of the bladder was occupied by a cauliflower growth in which haemorrhagic and sloughing areas were apparent. The whole of the organ except the trigone and neck of the bladder was resected. On microscopical examination the growth proved to be a papillomatous carcinoma. Gradual improvement occurred, and eight months later the patient was regarded as cured. When death followed, two months afterwards, from gangrene of the lung, no trace of any new growth could be detected, but a small newly formed bladder with a capacity of 30 c.cm., which had grown up round the trigone, was found, consisting of normal mucosa, submucosa, and muscular coat. In view of the frequency of recurrence in carcinoma of the bladder the author adds that the result in this case may be regarded as satisfactory.

648. Treatment of Osteomyelitis.

L. THORNTON (*Journ. Bone and Joint Surg.*, April, 1927, p. 294) describes a method of treating osteomyelitis of the lower third of the femur, based on simple physiological and mechanical principles, and leading to permanent healing. In the early stage of the disease drainage by incision is an emergency measure, and the more quickly this is performed the less extensive the disease and the less the prostration of the patient. After drainage a period of waiting ensues and the diseased bone undergoes a gradual process of repair. When an *x*-ray examination shows that a line of demarcation between the living and dead bone has become defined a radical operation is performed to remove all devitalized bone; by the use of a tourniquet the essential bloodless field is obtained. All sinuses must be eliminated; incomplete operations are useless. If the bone has been much weakened a plaster cast may be applied. The lower third of the femur is approached from the inner side as destruction is usually greatest on this side, and healing occurs here more readily.

649. Early Diagnosis of Cancer of the Stomach.

PUECH (*Bull. Soc. des Sci. Méd. de Montpellier*, February, 1927, p. 175) draws attention to certain symptoms which suggest commencing gastric carcinoma. Anorexia is present in 80 to 90 per cent. of cases; it is often selective in type and persists in spite of remedies. Pain is frequent but not marked. There is more often a sense of weight rather than real pain; it radiates towards the left hypochondrium and is not relieved by vomiting. The vomit may be mucous and non-acid, haemorrhagic, or alimentary, especially if the pylorus is affected; it usually occurs in the early morning (eaux du cancer). Intestinal troubles include constipation, diarrhoea,

and melaena, and there are general symptoms, such as loss of weight and strength, and pallor. During this dyspeptic phase a tumour can seldom be felt. The age of the patient and the absence of any probable cause of gastric trouble or any previous history of dyspepsia are points to be considered. If there is a previous history of chronic ulcer which has now become cancerous, it will be found that treatment which relieved the patient previously now fails. Laparotomy will not always settle the diagnosis, for enlarged glands may be present in chronic simple ulcer as well as in cancer, but in the first case they are red and inflamed, in the cancer hard and white. The neoplastic stomach is rather pale, in simple ulcer it is thicker.

650. **Periarterial Sympathectomy.**

E. BRESSOT (*Rev. de Chir.*, No. 1, 1927, p. 5) records the results obtained after operation in twenty-four cases of periarterial sympathectomy. All the patients were males and between 18 and 35 years of age. Operative treatment was only employed after other procedures had proved of no avail. The technique adopted was that described by Leriche; no difficulty was experienced in performing the operation and there were no complications. The syndrome as described by Leriche was always observed—namely, contraction of the artery at the site of decortication followed by vaso-dilatation in three to six days. The results obtained were good and persistent in cases of Raynaud's disease and in patients with blueness of the limbs, where the vascular spasm was the predominant feature. In chronic ulcers, not due to syphilis, the results were particularly satisfactory. In cases of fracture with delayed union and in patients afflicted with causalgia the operation also gave encouraging results. In one case of perforating ulcer of the sole of the foot and in some cases of varicose ulcer the operation proved to be of value.

651. **Treatment of Acute Pulmonary Abscess by Pneumothorax.**

ACCORDING to H. C. JACOBAEUS (*Acta Med. Scand.*, February 28th, 1927, p. 697) patients with pulmonary abscess are usually first treated medically, and not a few patients recover with expectant treatment consisting of rest in bed and expectorants. Salvarsan has proved of benefit in abscess caused by spirillosis. On the surgical border-line is bronchoscopic lavage, introduced by the Americans; this, however, is rather difficult to [illegible] special knowledge, taxes the patient's [illegible] and is only suitable for centrally situ[illegible] are two forms of surgical treatment: (1) thoracotomy with opening and drainage of the cavity; (2) treatment by collapse, either by induction of pneumothorax or by thoracoplasty. Treatment by pneumothorax entails the same risk as bronchoscopy—namely, rupture of the lung with subsequent fatal empyema, and it is therefore dangerous to treat superficial pulmonary abscesses by this method. Jacobaeus reports three cases of acute pulmonary abscess in which treatment by pneumothorax proved beneficial. While this number of cases is too small to permit of any general conclusions, he maintains that the patients probably regained their health by this treatment less tediously and more pleasantly than by thoracotomy, and probably more easily than by bronchoscopy. He adds that if pneumothorax treatment of acute pulmonary abscess is contemplated it should be begun early before firm adhesions form, and without attempting previous medical treatment. If clinical improvement is obtained in a very short time the pneumothorax treatment should be continued, since newly formed adhesions may yield subsequently. Should no immediate effect be obtained the pneumothorax should be aspirated as quickly as possible and some other surgical procedure adopted. A persistent pneumothorax is always an aggravating circumstance in other surgical operations.

652. **Treatment of Mammary Haemorrhage.**

F. J. KAISER (*Zentralbl. f. Chir.*, April 9th, 1927, p. 905) thinks that the occurrence of vicarious or concomitant menstrual haemorrhage from the nipple is so doubtful that it may be dismissed, and that any such haemorrhage must be regarded as due to undoubted carcinoma, polycystic degeneration, or intracanalicular cystic epithelioma. He has found records of a hundred such cases, and concludes that the condition cannot be so rare as Klose has stated. Kaiser has encountered two cases since March, 1925. One patient, aged 37, had had bleeding from the left nipple for three and a half years. Although a radical ablation with excision of both pectoral muscles, and skin, and removal of the axillary and subclavicular tissues was performed four days after she was first seen, the patient died a year later from metastases in the sixth dorsal vertebra and elsewhere. The tumour was an epithelioma. The other patient had observed bleeding from the left nipple for thirteen years; complete ablation was performed and there has been no recurrence. The tumour was a fibro-carcinoma. Kaiser believes that in every case of haemorrhage from the nipple an operation should be performed. If the disease appears to be clinically non-malignant, and the patient can be kept under observation afterwards, a conservative operation is generally advisable. If there is any clinical evidence of definite malignancy the treatment should be radical.

Therapeutics.

653. **Treatment of Cholera.**

J. W. TOMB and G. W. THOMPSON (*Trans. Roy. Soc. Trop. Med. and Hyg.*, April, 1927, p. 516) conclude from their observation of many thousands of cases of cholera that intravenous injections of hypertonic saline solutions have no specific beneficial action. With these injections the death rate was as high as when ordinary carminative cholera mixtures were exhibited—about 50 per cent. They admit that the loss of fluid and of salt, which led Rogers to employ hypertonic saline, calls for the supply of both, but claim that this is best accomplished by giving physiological salt solution. They advocate the early use of opium, and even regard its withholding as mischievous, their experience running parallel with that of Wall, who held that if the evacuations could be stopped early, the course of the disease would be arrested also, and that opium administered before the onset of collapse would often prevent it.

654. L. ROGERS (ibid., p. 522) maintains the specific advantages of hypertonic salines in cholera and quotes B. Moore as holding that the benefit is attributable to the high salt content produced in the blood causing the chlorides to combine with cholera toxins, and leading to their excretion through the kidneys. Rogers's full treatment combines the use of hypertonic salines with the alkalis and permanganate by the mouth.

655. R. C. ROBERTSON and C. C. P. ANNING (*Journ. Roy. Army Med. Corps*, May, 1927, p. 321) give an account of 309 Chinese and 47 European cases of cholera treated to a conclusion by Rogers's plan, the saline solution employed containing sodium chloride 120 grains, calcium chloride 4 grains, potassium chloride 6 grains, and water to one pint. Of the Chinese 40 died, and of the Europeans 8, giving mortality rates of 12.9 and 17.02 per cent. respectively. The Chinese cases were arbitrarily divided into groups according to severity. In the group "very severe," 57 cases had a fatality rate of 50.8 per cent.; for "severe" and "moderately severe" the rate was rather over 5 per cent., and the 59 "moderate" cases all recovered. Morphine was given to some and was found beneficial. In both series the disease was more fatal to women than to men.

656. **The Use of Ephedrine in Therapeutics.**

W. S. MIDDLETON and K. K. CHEN (*Arch. Int. Med.*, March 15th, 1927, p. 385) refer to previous investigations of the therapeutic action of eph[illegible] lak and Robertschek and of ([illegible] vol. ii, paras. 239 and 456). Th[illegible] experimentally the effects of ephedrine sulphate, or hydrochloride, after internal administration, as a mydriatic, and in the treatment of asthma. Fifty-eight observations were made on forty-one patients, the drug being given by the mouth (intramuscularly in six) in varying doses, but generally sufficient to determine tolerance by eliciting mild toxic symptoms; the therapeutic dose advocated for oral administration is 60 to 90 mg., or from 1 to 1½ grains. With few exceptions this was found to cause an average rise of systolic blood pressure of 28.5 mm. of mercury, lasting about five hours; the diastolic pressure was also raised, averaging 12.5 mm., the pulse being more frequently accelerated than slowed. Of the untoward symptoms resulting from larger doses, diaphoresis, tremor, extra-systoles, tonal arrhythmia, palpitation, weakness, nausea, vomiting, and dizziness were among the most common, with, more rarely, tachycardia, restlessness, mydriasis, headache, insomnia, dyspnoea, and drowsiness. The authors consider that the drug is contra-indicated in cases of cardio-vascular disease or deficient circulation. A 10 per cent. solution of the sulphate with 0.1 per cent. homatropine hydrobromide was found to produce rapid, almost maximum, dilatation of the pupil, with brief paresis of accommodation and disappearance of the light reflex; it was also shown to be useful as a mydriatic for routine ophthalmoscopic examinations. The effect produced by atropine solution alone was slower in onset and development, though it lasted longer than an ephedrine-atropine combination. The efficacy of the drug in the treatment of bronchial asthma was tested in twenty-five unselected cases, doses of 50 to 100 mg. being given by the mouth; the

attacks were controlled in nine cases and improved in eight, but the remainder showed negative or inconclusive results. K. K. CHEN (*Ibid.*, p. 404) reports the results of a comparative experimental study of the effects produced by ephedrine, pseudo-ephedrine, and phenyl-ethylamine. The last of these, when injected intravenously, was found to act more intensely but for a shorter time than the first. Pseudo-ephedrine was shown to be weaker than ephedrine, but its action persisted for the same length of time.

657. Ephedrine in the Treatment of Bronchial Asthma.

G. F. MUNNS and C. A. ALDRICH (*Journ. Amer. Med. Assoc.*, April 16th, 1927, p. 1233) have used ephedrine sulphate in the treatment of twenty-two children with bronchial asthma, and report that in twelve cases full relief was afforded to patients in the paroxysmal stage, or with persistent cough, usually within thirty to forty-five minutes after the first dose. In four cases the amelioration was only partial, and in six cases the drug had no apparent beneficial effect. The minimum and maximum doses of ephedrine sulphate given by the mouth were 12 and 50 mg. respectively. In some instances the drug was given regularly for four hours, in others only as indicated by the symptoms. Nausea was caused in four cases, in two of which no benefit resulted. The relief seldom lasted less than four hours and often persisted for a day. No evidence of the establishment of tolerance to the drug was obtained. The authors think that ephedrine may, therefore, be recommended as a valuable remedy, particularly in milder cases of bronchial asthma in children when it relieves the cough.

658. Therapeutical Value of Invert Sugar.

W. SCHEY (*Wien. klin. Woch.*, March 31st, 1927, p. 421) has used continuous intravenous drop infusion of a 10 per cent. solution of invert sugar known as kalorose for eighteen months in the pre-operative and post-operative treatment of moribund patients with such conditions as perforated duodenal ulcer and peritonitis, and found it of greater value than isotonic and hypertonic saline infusions, with and without adrenaline, similarly administered. Its stimulant action on the heart was effective when camphor, caffeine, strychnine, digalen, and intravenous adrenaline saline had failed. The technique employed was as follows. An ante-cubital vein was exposed and a glass cannula with two right-angled bends was tied into the vein with a silk ligature; 500 c.cm. of the solution were run in at body temperature, and the dropping apparatus was then so adjusted that the solution flowed at the rate of one drop every three or four seconds. The cannula was kept in position with gauze swabs, strapping, and a bandage, and the arm was fixed in almost complete extension on a splint. The flask was refilled from time to time, though it was not found necessary to warm such subsequent additions, and the infusion was continued thus for several days. One patient received about 800 grams of sugar in 100 hours of continuous infusion, insulin being injected meanwhile. Schey adds that the apparatus needs careful watching; it should be disconnected, without attempts at restarting, should the solution stop flowing, because of the risk of embolism from a possible thrombus in the vein.

659. Bismuth in the Treatment of Arterial Hypertension.

A. LAMA (*Il Policlinico*, Sez. Prat., May 2nd, 1927, p. 648) has collected a series of patients known formerly to be syphilitic who were suffering from marked arterial hypertension (above 250 mm. of mercury). He reports that after treatment with bismuth salts the arterial pressure indicated by the sphygmomanometer fell and remained lowered for some time, even for months. In other cases of marked arterial hypertension, in which there was no history of syphilis, and the Wassermann reaction was negative (the so-called essential arterial hypertension), and in cases of vascular sclerosis, particularly of the renal type, he tried the same treatment and obtained a marked diminution of the arterial blood pressure, which, if not permanent, was at least very persistent. He employed suspensions of the tartrate or oxide of bismuth, or solutions of the sodium potassium bismuthyl tartrate, or the oxyhydrate of bismuth. He has found benefit result in some cases from two or three courses of treatment, with a month's rest between each.

660. Serotherapy in Scarlet Fever.

V. BIE, A. LARSEN, and M. S. ANDERSEN (*Acta Med. Scand.*, April 30th, 1927, p. 238) have tried three methods of serum therapy in scarlet fever: (1) a polyvalent streptococcal serum; (2) the serum of scarlet fever convalescents; (3) a specific serum of *S. scarlatinae*. They now report in detail several cases treated by each method. In the preparation of the polyvalent serums several strains of streptococci—obtained from the throat, the pus of ear and gland infections, and the blood—were used. As regards the second method they state that the blood of the convalescents should be taken fifteen days after the temperature has become normal, and both Dick and Wassermann tests should be made on the serums. They think that the failures of this method may be due to insufficient dosage, and recommend doses of 20 to 25 c.cm. for children up to 5 years of age, 25 to 35 c.cm. between 5 and 12 years, and 40 to 60 c.cm. for older children and adults. Specific serums were prepared according to the technique of Dochez, and the one employed by the present authors contained 30,000 skin units per cubic centimetre. This serum was usually given intravenously. Each method has proved satisfactory, but the convalescent and specific serums gave the best results. The drawback to the employment of convalescent serums is the difficulty of obtaining suitable blood and the necessity of laboratory collaboration; the authors, therefore, recommend specific serums.

Ophthalmology.

661. A Scissors-Needle for Discission.

A. KOLEN (*Amer. Journ. Ophthalmol.*, March, 1927, p. 186) describes the scissors-needle for discission of thick capsular membranes which he has devised on account of the difficulty which sometimes occurs in making an aperture in a dense capsular membrane, when discission with two needles has certain obvious disadvantages. The needle is made in two halves, which closely adjoin each other in the plane in which lies the broad profile of the needle. The two blades are fastened together by a small screw, and they can be separated by a lever attached to the shaft of the handle. After finishing the cutting the lever is released, the blades come together again, and the instrument can be easily withdrawn.

662. Glaucoma in Morgagnian Cataract.

A. KNAPP (*Arch. of Ophthalmol.*, March, 1927, p. 124) describes two cases of the rather infrequent association of glaucoma with Morgagnian cataract. Gifford believes that the degenerating cortex of the lens causes toxic products which are absorbed and produce glaucoma, but Teingold thinks that the irritation of the ciliary body by the subluxated shrunken lens is the only plausible explanation. In Knapp's two cases the local condition in the Morgagnian cataract seemed to be the cause of the rise of tension as the cortex had become completely absorbed, and he thinks that mechanical irritation of the ciliary processes by the displaced nucleus is the main factor in producing the rise of tension. As regards preventive treatment he considers it wiser not to allow a cataract to become hypermature. If this has occurred and glaucoma is set up it is best to treat the glaucoma medically and then extract the lens, preferably in its capsule, when the eye is quiet.

663. Conjunctivoplasty.

JOSEPH L. MCCOOL (*Amer. Journ.* [illegible] 1927, p. 113) calls attention to the va[illegible] in progressive types of corneal ul[illegible] the case of a woman, aged 58, who had a large and progressive marginal ulceration of the left cornea. As nothing seemed to check the spread of the ulceration it was decided to perform conjunctivoplasty. A flap of conjunctiva was dissected from above the cornea and one from below. These two flaps were drawn over the cornea so as to cover it except for a small central interval. The lower flap receded to its original position; the upper one did not entirely retract, but became incorporated in the corneal scar. The effect upon the corneal ulceration was, however, very marked and seemed definitely to start the healing process.

664. Treatment of Corneal Abrasions.

E. N. HUGHES (*Brit. Journ. Ophthalmol.*, April, 1927, p. 145) has found Locke's solution useful in corneal conditions, especially those arising from trauma. This solution contains the mineral salts of the blood with the addition of dextrose, the complete formula being:

Sodium chloride	0.9 part
Sodium bicarbonate	0.05 ,,
Potassium chloride	0.042 ,,
Dextrose	0.1 ,,
Calcium chloride	0.025 ,,
Distilled water	to 100

In one rather striking case of trauma a strip of corneal tissue 3 mm. wide and 5 mm. long had been gouged from the central part of the cornea; in its deepest part the wound penetrated to half the thickness of the cornea. The strip of cornea was replaced in position, Locke's solution was applied hourly, and the eye was covered by a light pressure bandage during the intervals between bathing. In a week's time the strip had reunited and only a very slight opacity was present at the edges, the strip of cornea itself being quite clear.

Obstetrics and Gynaecology.

665. Treatment of Ovarian Pain.

J. LHERMITTE and R. DUPONT (*Gynécol. et Obstét.*, March, 1927, p. 161) describe their method of denervation of painful and tender ovaries. They accept the descriptions of Hovelacque and Segond, according to whom the sympathetic filaments innervating the ovary come from the renal plexus, and during their descent with the ovarian artery receive communications from the intermesenteric plexus. There is no communication between the nerves of the uterus and those of the ovary, which enter in the middle third of the hilus. The nerves are separated by a comparatively large space from the artery. It has seemed to Lhermitte and Dupont logical in cases of pain of ovarian origin to excise a portion of the nerve filaments at the hilus of the ovary, after incision (parallel to the long axis of the ovary) of the posterior face of the broad ligament. This denervation is regarded as preferable to division of the pre-sacral plexus or hypogastric periarterial sympathectomy, although these procedures may to some extent remove pain by severing reflex nervous connexions of the ovary. The authors recommend denervation of the ovary on both sides, and record eleven instances in which great relief of pain has followed, mostly in cases in which the ovaries were sclero-cystic and in which also uterine malposition, appendicitis, or other morbid lesions were found and treated at operation. Neuromata resembling those of operation scars have been described in the hilum of the sclero-cystic ovary by Roux and in the ovarian stroma by Lhermitte and Dupont.

666. Chorion Epithelioma of the Fallopian Tube after Ectopic Pregnancy.

P. KLEIN (*Arch. f. Gynäk.*, January 31st, 1927, p. 662) records the case of a nullipara, aged 24, who had continuous utero-vaginal haemorrhage of variable, but on the whole moderate, intensity for three and a half months; no menstrual period had been missed. Severe haemorrhage followed a vaginal examination, and recurred two days later. On admission to hospital a reddish-black bleeding tumour the size of an olive was found attached by a short thick pedicle to the anterior vaginal wall; through the posterior and right vaginal fornices a tender tumour the size of a small orange was palpable. The vaginal tumour broke off readily, and was proved by microscopic examination to be a chorion epithelioma. The right adnexa were extirpated, a tubal haematocele being removed intact; this contained old blood clot, with microscopical evidence of organization in the tissue connecting it with the tubal musculature and of a chorion epitheliomatous neoplasm. On the sixth day after operation a sharp vaginal haemorrhage occurred, and a bleeding vaginal tumour the size of a hazel nut was removed from the site of the original vaginal tumour; microscopical examination again showed chorion epithelioma. A third recurrence in the same place led to alarming haemorrhage ten days later, and after its excision an *x*-ray application was made locally. Shortly afterwards haemoptysis occurred, and *x*-ray evidence of pulmonary metastases was found. Several *x*-ray applications to the chest followed, and ten months later the patient felt well and no morbid condition could be found in the genital organs, or in the lungs by radiography. The conclusion that this case was one of chorion epithelioma following tubal pregnancy, and not of a chorion epitheliomatous metastasis in the tube after uterine pregnancy, is drawn from the history, the histological examination of the tube, and the absence of gross change in the uterus. Klein has found records of fifteen other cases of tubal chorion epithelioma following tubal pregnancy; all proved quickly fatal from recurrence or metastases. Regression of lung metastases has been occasionally reported after uterine chorion epithelioma, and it is known that other metastases sometimes regress spontaneously after removal of the primary tumour.

667. Severe Ovarian Haemorrhage in Young Girls.

A. HERRMANN (*Zentralbl. f. Chir.*, April 16th, 1927, p. 976) reports that among 530 appendicectomies in women and girls he has encountered two cases of haemorrhage from the corpus luteum resembling appendicitis. A girl, aged 17, previously healthy, had a sudden attack of pain in the right iliac fossa, with vomiting and constipation; she had menstruated three weeks previously. There was pain on pressure over McBurney's point and the temperature was 100.5° F. Laparotomy revealed 30 c.cm. of black blood in the region of the caecum and right adnexa, which had escaped from a follicle in the right ovary. The bleeding point was excised and sutured, the appendix, though healthy, was removed, and the wound was closed. Another girl, aged 16, had a sudden attack of severe cramp-like pain in the right iliac fossa with vertigo and constant vomiting. She had menstruated three weeks previously. She was collapsed and pale, and the temperature was over 101°. There was severe pain on pressure and muscle-guarding over the right iliac fossa. At operation 50 c.cm. of black fluid blood and clots was found in Douglas's pouch and the right adnexal region; this came from a follicle in the right ovary, which was excised and sutured. Herrmann has found records of eighty-nine similar cases, and states that the differential diagnosis between appendicitis, haemorrhage from an ovarian follicle, and a ruptured tubal pregnancy may be difficult. The etiology is obscure, and there is certainly more than one possible cause. There was no question of the possibility of ovarian pregnancy in Herrmann's two cases, and many writers have recorded similar cases in which this condition could be excluded. Other causes are: inflammatory changes, heavy lifting, injuries, straining at stool, coitus, hyperaemia, and tumours. Haemorrhage occurs, in the majority of cases in the third week of the intermenstrual period, in the minority at other times.

668. Complete Atresia of the Vagina.

D. FERRACCIU (*Studium*, April 20th, 1927, p. 156) records three cases of complete atresia of the vagina. In the first the condition was the result of neglected laceration of the genitals occurring in labour; in the second case it was probably due to the use of caustic fluids in antiseptic vaginal douches; and in the third it was congenital. In all three cases the closure of the vagina had produced the same result—namely, the development of haematometra and haematosalpinx with the characteristic train of symptoms inherent in such lesions. Cases of complete vaginal atresia of puerperal origin are very rare. Prophylaxis consists in paying special attention to the patient, not only during the expulsive period of labour, but also in the early stage of the puerperium. The author adds that it should also be borne in mind that too prolonged immobilization may favour the adhesion of the lacerated tissues to one another.

669. Diathermy in Gynaecology.

B. S. TEN BERGE (*Nederl. Tijdschr. v. Geneesk.*, April 16th, 1927, p. 2110) has employed coagulation by diathermy in the following gynaecological conditions: (1) For diminishing the risk of wound infection in operations for cancer of the cervix, or total hysterectomy (13 cases). (2) In inoperable cancer of the cervix (7 cases). (3) In cancer of the labia and clitoris (1 case of each). (4) For cervical biopsies. (5) For removal of polypi. (6) In the treatment of ectropion, erosions, and chronic inflammation of the cervix. The primary mortality in hysterectomy for cancer of the uterus is high, ranging from 10 to 20 per cent.; death is due to cellulitis, peritonitis, septicaemia, or pyaemia, the infection arising from ulceration of the malignant growth. Since July, 1925, Ten Berge has treated the cancer before removal by diathermy, with the result that all the patients recovered, except one who died from peritonitis.

670. Sudden Death in Eclampsia without Convulsions.

R. POHL (*Zentralbl. f. Gynäk.*, April 9th, 1927, p. 913) records the case of a 3-para, aged 40, who died immediately after admission to hospital, moribund and comatose, during the sixth month of pregnancy. She had noticed oedema of the legs two days previously, followed by headache and vomiting; the coma was of a few hours' duration at the most, and there had been no convulsions. The urine contained 18 per cent. of albumin, as well as granular and hyaline casts. The diagnosis of eclampsia rested on characteristic microscopic findings in the liver and kidneys. The brain was soft; its substance was free from haemorrhages, but the lateral and fourth ventricles were filled with blood clot.

671. Haemorrhoids in Pregnancy.

W. A. FANSLER (*Minnesota Med.*, April, 1927, p. 212) refers to the fact that the engorgement of the pelvic vessels in pregnancy is apt to aggravate if not induce rectal complications. Some of these are best treated by palliative measures, the chief of which is the regular administration of laxatives. In patients with a previous history of normal pregnancies an early operation is indicated and is free from danger. In the later months such operation, though comparatively safe, should if possible be postponed. When there is a history of previous miscarriage or of systemic disease an operation is always contraindicated; in some acute cases, however, such as parietal abscess and strangulated or necrotic haemorrhoids, an operation becomes a necessity: it *should* be performed with as little delay as possible and under local anaesthesia. In the case of internal haemorrhoids the author advises injections of quinine urea hydrochloride; he finds such to be less disturbing than an operation and usually as effective.

672. Determination of the Relation Between the Foetal Head and the Pelvic Inlet.

E. D. RESNIK (*Surg., Gynecol. and Obstet.*, April, 1927, p. 553) describes a method of estimating beforehand the likelihood of the foetal head being able to enter the pelvis at birth. After determining the position, presentation, and posture of the child, and the situation of the anterior shoulder, the obstetrician passes one finger up the rectum to the level of the ischial spines, and places the palm of his other hand on the most dependent portion of the abdomen, as nearly over the anterior shoulder of the foetus as possible. With this hand this part of the abdomen is raised rather forcibly towards the mother's head, the hand sliding over the abdomen to a point just above the umbilicus, from which strong pressure is exerted towards the mother's spine. If the foetal head is not too large it advances into the pelvic inlet, often as low as the ischial spines, thus providing reasonable assurance that it will be able to engage during labour. The mechanism of this procedure is described and illustrated by diagrams, and the author states that he has found it very useful and reliable in many cases.

Pathology.

673. The Nature of the Vasomotor Mechanism.

OBSERVATIONS of the results following their operations on the sympathetic system lead R. LERICHE and R. FONTAINE (*Presse Méd.*, April 16th, 1927, p. 481) to the deduction that the classical theories of vasomotor mechanism need revising. These operations included removal of the entire cervical chain and of various ganglia, and section of different nerves for various conditions, including angina, scleroderma, and Raynaud's disease; they were supplemented by experiments on dogs. The authors classify their findings in the following three groups. (1) Section of all the so-called vasomotor nerves of a limb never causes vasomotor failure or lasting disturbance. No operations on the sympathetic produce vaso-paralysis, but are rapidly followed by an active, though temporary, vaso-dilatation, which from the one limb affected spreads to the others. (2) Section of certain sensory nerves, freezing of mixed nerves, and extirpation of neurones cause the same phenomena of active vaso-dilatation but not of paralysis or vaso-constriction. (3) After section of the medulla, which causes paralytic dilatation, vasomotor reactions persist. The authors consider these facts incompatible with the conception of physiologists that centrifugal vasomotor nerves run from the medulla to the periphery, the one carrying vaso-constrictor, the other vaso-dilator impulses. From their operations on communicating branches and on different lateral chains they do not believe that the vaso-dilators are exhausted before reaching the periphery and their action spent in the ganglia; they suggest instead that the periphery is the site of vasomotor actions which regulate the local circulation. The existence of vasomotor centres in the arterial walls is admitted, and it is possible to suppose that between these intra-arterial and the ganglionic and medullary centres there is a sensory connexion through fibres of an ortho- and anti-dromic conduction. The authors contend that the conception of the sympathetic system being purely centrifugal is no longer tenable.

674. Vascular Reactions of the Skin to Injury.

T. LEWIS and IRIS M. HARMER (*Heart*, April 20th, 1927, p. 19) have obtained evidence that the response of the cutaneous vessels to mechanical stimulation is due to the release of minute quantities of a substance resembling histamine. This acts locally on the endothelial vessels, causing dilatation, and on the sensory nerve endings, producing an axon reflex and thereby dilating contiguous skin arterioles. This substance is present only in infinitesimal quantity, therefore its source has not been determined. Believing that the local wheal is due to the release of a histamine-like substance, it was thought that extensive stroking of the skin of susceptible persons might liberate this substance in sufficient quantity to produce a recognizable general vaso-dilatation. This was found to occur in four patients with urticaria factitia. Firm stroking of the back with a comb produced between 70 and 130 wheals. Vaso-dilatation began shortly after the stroking had ended, reached a maximum in about six minutes, and more slowly declined. The reaction generally was indistinguishable from that caused by comparable hypodermic doses of histamine. Subjects whose skins are normal do not react to stroking. These observations provided direct evidence that in factitious urticaria a histamine-like substance is released in the skin and passes gradually into the general circulation. When there was an extensive distribution of wheals over the trunk the quantity of this substance released was equivalent to about 0.1 mg. of histamine base. One-third of this quantity of histamine base given hypodermically yields a recognizable general reaction. The concentration of the released substance in wheal fluid is calculated, in terms of histamine, to be about 1 in 1,500,000; this is in close agreement with previous determinations by other methods.

675. T. LEWIS and H. M. MARVIN (ibid., p. 27) state that the vascular response of the skin to injury consists of (1) a local dilatation of the minute blood vessels; (2) an increase in the permeability of their walls, leading to the formation of skin wheals; and (3) a widespread dilatation of the neighbouring arterioles. The first two effects are due to direct action of a histamine-like substance on the vessels, the third is due to an axon reflex, following sensory nerve paths. If heat, cold, or friction be applied for a longer period the local wheal is replaced by a blister. As the result of numerous experiments, the authors state the following conclusions. When the skin reacts by local reddening, wheaing, and a widespread flare, or when blistering follows, the vascular skin reactions are the result of the local release of a histamine-like substance. Antidromic impulses passing along sensory nerves cause vaso-dilatation by releasing a vaso-dilator substance from the tissues which the sensory nerve supplies. Nervous impulses are said to be capable of influencing the size of peripheral vessels in one of two distinct ways—namely, by a more or less direct action, and by an indirect action in which a released vaso-dilator substance is the immediate cause of vaso-dilatation. Herpes zoster is attributed to antidromic impulses passing down the sensory nerves, [illegible] skin, substances of a histamine-like nat[illegible] that antidromic impulses are concern[illegible] abolic or secretory activities of tissues supplied by them and that trophic lesions are due to disturbances of this control.

676. The Etiology of Scarlet Fever.

B. L. PALANTE and V. J. KOUDRIAVTZEVA (*C. R. Soc. de Biologie*, May 13th, 1927, p. 1218) endeavoured to repeat Ramsine's work on the filterability of pathogenic streptococci. Ramsine claimed to have isolated streptococci from mice injected with culture filtrates, and to have grown streptococci on artificial media inoculated with these filtrates; he concluded that streptococcal toxin contained filterable forms of this organism. The authors' cultivation experiments with filtrates of different strains of streptococci through a Chamberland L5 candle were completely negative. When these filtrates were injected into mice, however, it was sometimes possible to recover a streptococcus from the peritoneum. This they regard as quite inadequate proof of the presence of a filterable form of streptococcus in the inoculum. They bring evidence to show that streptococci are not uncommon in the blood and tissues of normal mice; and that when some foreign substance, such as dead Friedländer bacilli, is injected, these organisms tend to accumulate at the local site; they term them "microbes de sortie." Their conclusion is, therefore, that the presence of a filterable form of streptococcus cannot be demonstrated by biological methods. S. ZLATOGOROFF, V. KOUDRIAVTZEVA, and B. PALANTE (ibid., p. 1220) bring this conclusion to bear on the etiology of scarlet fever. Since, according to them, it is possible to reproduce in monkeys and rabbits a condition closely similar to scarlet fever by the injection of streptococcal cultures and of streptococcal filtrates deprived of toxin, and since streptococci themselves are unable to pass through filters, it is evident that experimental scarlatina must be due to a filterable virus. This virus they claim to have cultivated in Tarozzi-Noguchi medium. They state that it grows in the form of minute diplococci, not exceeding 0.1 μ in diameter. Cultures of the fifth or sixth generation on inoculation into rabbits have reproduced typical experimental scarlatina. They consider these minute diplococci to be the visible form in culture of the filterable virus, and to be absolutely distinct from streptococci.

677. Duodenal Intubation in Typhoid Fever.

N. HENNING and A. LECHNER (*Münch. med. Woch.*, April 8th, 1927, p. 579) performed duodenal intubation for purposes of bacteriological diagnosis in thirty-six cases of typhoid and paratyphoid fever. In 26 per cent. typhoid or paratyphoid bacilli were found in the duodenal fluid and in 53 per cent. in the bile. In two cases the presence of typhoid or paratyphoid bacilli could only be detected by duodenal intubation. In only a relatively few cases could large quantities of bacilli be found in the duodenal fluid or bile. This fact, is not due to the bacteriological action of the duodenal fluid, as the authors found that typhoid bacilli were frequently unaffected after a prolonged contact with duodenal fluid.

EPITOME OF CURRENT MEDICAL LITERATURE.

Medicine.

678. Angina Pectoris and Dilatation of the Right Side of the Heart.

S. WASSERMANN (*Wien. Arch. f. inn. Med.*, March 15th, 1927, p. 1) reports cases to show that angina pectoris and cardiac dilatation may co-exist, or even alternate in the same patient; cardiac dilatation may follow an attack of angina pectoris after the acute pain has subsided. Many cases of typical angina pectoris are closely associated with dilatation of the right side of the heart, and consequent hepatic congestion. In arterio-sclerotic patients with the classic symptoms of angina pectoris, including dyspnœa, pain, and sense of oppression behind the sternum, and radiating pains in the left arm or in both arms, swelling of the liver is usually present and is frequently pathognomonic. Wassermann describes five non-syphilitic cases which were under observation for periods of two to three years. The ages of the patients ranged from 49 to 58, the average being 53.8 years. All had occasional anginal attacks with sensations of intrathoracic pressure and pain radiating from the left arm or down both arms. The heart sounds were quite pure, but usually weak. One patient died suddenly, fifteen months after his first admission. In every case the liver was distinctly enlarged and usually palpable. Wassermann describes two cases in which angina pectoris was associated with syphilis. A man, aged 65, suffered from syphilitic mesaortitis; the liver was much enlarged. His anginal attacks were not relieved by nitrites nor by opiates, and he suffered severe pain for some hours before death. The other patient, a man aged 50, had had syphilis nineteen years previously, but his Wassermann reaction was negative. He suffered from severe anginal attacks. In October, 1923, the left depressor nerve was divided. Following this the patient's symptoms were relieved for three years, then the anginal attacks recurred. The pains radiated down both arms, and Cheyne-Stokes respiration was present for some hours before death. The liver was much enlarged. The patient died three years after his first admission. The necropsy revealed chronic endarteritis deformans, affecting especially the coronary arteries, extensive myocardial degeneration, and thrombosis in the apical portion of the left ventricular wall. Wassermann concludes that in typical angina pectoris there is an enlargement of the liver connected with failure of the right side of the heart of the hepatic congestion type. Although these failures of the right side of the heart had homolateral clinical sequelae, the anginal attacks account for the contralateral coronary sclerosis. Failure of the right heart and angina pectoris are therefore associated in many cases. All these sequels may occur, *mutatis mutandis*, in cases of syphilitic angina pectoris. Each case of angina pectoris demands the most careful examination of the liver, including its functional efficiency.

679. Syphilis and Trauma.

G. ELIET (*Thèse de Paris*, 1926, No. 582), who records twelve illustrative cases, states that trauma of any kind may give rise to specific lesions in subjects of acquired or hereditary syphilis in any part of the body, especially the skin, bones, and joints. The following varieties of traumatic syphilis may occur: (1) Cases in which a very slight trauma imparts a special intensity and morphological character to the syphilitic lesions at the site of the trauma. These cases are chiefly seen in the secondary stage. (2) Cases in which trauma, usually of considerable violence and applied only once, gives rise to the appearance of syphilitic lesions. These cases, which are the most important in practice, are chiefly found in tertiary or hereditary syphilis. They are often of forensic interest owing to the occurrence of accidents in workmen. (3) Cases in which a slight trauma is either permanent or has been constantly repeated, as in occupational injuries, and tics. Cases may also occur in which the results of a trauma, such as a scar or callus, may serve as a localizing point for syphilitic lesions. Before deciding that there is a causal relation between a trauma and a syphilitic lesion the following points must be established: (1) the reality of the trauma, its date and situation; (2) the existence in the patient of hereditary syphilis or acquired syphilis which has reached the secondary stage at least; (3) a definite interval between the application of the trauma and the appearance of the lesions; (4) the obvious and rapid efficacy of appropriate antisyphilitic treatment. An industrial accident may give rise to the appearance of traumatic syphilis which requires antisyphilitic treatment, and in such cases the workman will receive the same benefits as if the accident alone was responsible for the lesion. The two following explanations have been offered for the lesions of traumatic syphilis. The spirochaetes circulating in the blood become arrested in the injured regions in which there is a retardation or arrest of the capillary circulation (G. Milian). Less frequently the symptoms are due to a local reactivation of dormant spirochaetal foci by the trauma (C. Simon).

680. Cardiac Asthma.

M. H. KAHN (*Amer. Heart Journ.*, April, 1927, p. 424) recognizes two essentially different types of cases of cardiac asthma: (1) those due to pulmonary stasis with right ventricular deficiency, and termed by him "pulmonary asthma"—this type also occurs in the terminal stages of left ventricular failure; (2) those depending upon left ventricle deficiency alone; here irritability of the respiratory centre produces reflex paroxysms of breathlessness, and the term "cardiac asthma" is restricted to this condition. Kahn suggests a clinical classification of the various forms of dyspnœa in heart disease, using a physiological basis. The organic conditions underlying pulmonary asthma are those marked deficiencies that develop in chronic myocardial or chronic valvular disease where the heart is progressively failing. The attacks occur after strain of any kind, and the dyspnœa is both inspiratory and expiratory, with wheezing, congested bases, and cyanosis. The condition may go on to pulmonary oedema. Cardiac asthma occurs chiefly with the aortic and coronary lesions of persons in the later decades of life. The attacks are sudden, often nocturnal, and associated with pallor, cold sweatings, and a feeling of anxiety. The patient may leap from his bed and gasp for breath. A diagnosis has to be made from coronary thrombosis. The symptoms are attributed to stimulation of the respiratory, vasomotor, and vagal centres in the brain by anoxæmia due to weak ventricular contractions. Such attacks are relieved by morphine, which depresses the centres, or by nitrites, which improve the local circulation. Pulmonary and cardiac asthma often coexist. Kahn gives short descriptions of cases of both forms of asthma and discusses the differential diagnosis.

Surgery.

681. Primary Sarcoma of the Appendix.

E. CAPECCHI (*Il Policlinico*, Sez. Chir., April 15th, 1927, p. 153) records an instance of this uncommon condition. A boy, aged 8, was admitted into hospital as a case of appendicular colic. He had suffered from gradually increasing pain in the right iliac fossa for the previous month. The temperature had not been raised until the day before admission. The father suffered from chronic appendicitis, and a brother had died at the age of 7 from sarcoma of the caecum. There was marked tenderness over McBurney's point and slight dullness. Laparotomy was performed and a little serofibrinous fluid let out; the distal third of the appendix was involved in a tumour as big as a hen's egg. The whole mass was removed and the patient left the hospital well. The growth proved to be a polymorphic-celled primary sarcoma of the appendix. The author discusses other malignant tumours of the appendix. Carcinomata are commoner than sarcomata; thus out of 120 cases of new growth of the appendix 114 were carcinomata and only six sarcomata. The first recorded case of sarcoma was published by Hastings Guildford in 1893. Nearly all the cases occur in young subjects. The prognosis is said to be fairly good if removal is done early and if the growth is not too close to the caecum.

682. Sphincter Dilatation after Laparotomy.

A. HERRMANN (*Deut. Zeit. f. Chir.*, April, 1927, p. 210) refers to the well known fact that intensive physical activity has a stimulating effect upon peristalsis, while any unaccustomed confinement to bed tends to produce constipation. During illness this tendency is aggravated, while when the patient has had laparotomy performed the condition is still worse—peristalsis is feeble or absent, flatus accumulates, producing distension, while pain in the operation wound when any attempt at straining is made prevents a successful effort to defecate or pass flatus. The patient is unable to assume a natural position, while the tympanitic distension increases pain and retards peristaltic action. Herrmann believes that retention of urine, so common after abdominal operations,

is also due to absence of intestinal movements, the patient's inability to endure any strain on the sutures in the abdominal wound, and the reflex spasm of the sphincters induced by distension. During the last eighteen months he has resorted to dilatation of the sphincter ani in over a hundred cases of operations for such conditions as peritonitis and intestinal resection. He prefers to dilate the sphincters with both index fingers, inserted for one or two minutes, rather than to use instruments, as he believes that the latter may produce permanent incontinence. He finds that shortly after the dilatation the patient usually evacuates faeces and flatus, and is then able to pass urine.

683. Tonsillectomy in Rheumatic Fever.

W. H. ROBEY and L. M. FREEDMAN (*Boston Med. and Surg. Journ.*, April 14th, 1927, p. 595) have investigated 454 cases of rheumatic fever, chorea, and rheumatic heart disease in order to ascertain whether any relation existed between them and tonsillectomy. They conclude that complete enucleation is the best preventive of rheumatic fever and heart disease, and consider that tonsillectomy should be performed when there is a history of repeated sore throats, even when the tonsils appear normal; tonsils diseased in appearance require enucleation even in the absence of sore throats. Since incomplete tonsillectomies leave the patients in as dangerous a condition as before, the operation should be regarded as a major one, only to be performed by those having experience. The fact that rheumatic heart disease may appear after tonsillectomy does not prove, the authors add, that the operation has failed as a preventive, but rather points to the fact that its delay has made the cardiac damage possible. In 60 cases of acute rheumatic fever tonsillectomy was performed during the height of the attack, after all medical measures had been tried and had failed, with prompt subsidence of fever and joint symptoms. This result encouraged the authors to resort to operation as soon as it could be shown that the tonsil was the port of entry; they believe that such treatment would diminish the possibilities of cardiac involvement. Although some advocate deferring the operation until the acute attack has subsided, the authors quote Starling as supporting their advocacy for operation early in the infection, since the longer the attack lasts the more extensive will be the results.

684. Hypernephroma.

G. NISIO (*Il Policlinico*, Sez. Chir., April 15th, 1927, p. 182) reports a case of hypernephroma and discusses the subject with special reference to diagnosis. About 86 per cent. of the malignant growths of the kidney, according to Kummel, are hypernephroma and usually occur in the fourth or fifth decade of life. They are sometimes benign in course, and sometimes diffuse rapidly, or they may first appear as a metastatic growth in a bone before there is any evidence of involvement of the kidney; these metastatic growths may pulsate. The comparatively symptomless evolution of hypernephroma makes its diagnosis difficult. Some enlargement of the kidney and haematuria may be slow to appear; if the enlargement is at the upper pole of the kidney, especially on the right side, it may not be easy to feel it. The presence of a variocele on the same side as the tumour is suggestive, but it is by no means a constant symptom, and is in any case a late one. The oval cells reported by Leotta as occurring in the urine are said to be characteristic of the disease. Functional and pyelographic examination is often very useful, and radiographic examination made after gas insufflation of the renal capsule is helpful. A haematuria coming on in an adult, without pyuria, tubercle, or vesical lesions, should suggest growth of the kidney. The greater or less delay in the appearance of colouring substances for each separate ureter is rather an uncertain test; in the author's case the coloured fluid appeared earlier on the affected than on the sound side. Of more value is the specific gravity, molecular concentration (cryoscopy), and estimation of the urea and chlorides. Prognosis after nephrectomy depends on how far the growth has extended.

685. Early Paget's Disease.

G. BARBIER (*Bull. Soc. Française de Derm. et de Syph.*, March, 1927, p. 150) describes the case of an apparently healthy woman, aged 52, who had had a slight excoriation of the right nipple for five months. When an adherent scab had been removed a small pink moist erosion was seen. Treatment by tar ointment produced only temporary healing. In spite of the small area of the lesion, its appearance and intractability under treatment suggested Paget's disease, and histological examination showed invasion of the galactophorous ducts with cystic dilatations. Barbier suggests that the disease of the nipple is secondary to the subjacent duct epithelioma.

Therapeutics.

686. Vaso-constrictor and Vaso-dilator Drugs in Therapeutics.

C. ABADIE (*Presse Méd.*, March 7th, 1927, p. 579) discusses the successful treatment, by twenty subcutaneous injections of adrenaline, of a man who suffered from repeated attacks of hemicrania associated with unilateral rhinorrhoea and watering of the eye, due probably to sudden vaso-dilatation. He emphasizes the value of drugs acting on the vasomotor system in the differential diagnosis of such conditions as chronic glaucoma and optic atrophy, and advocates the therapeutic use of atropine in cases of optic atrophy due to spasm of the retinal arterioles. He claims that injection of 1 mg. of atropine into the orbital cavity or subcutaneously will always improve the residual vision in cases of spasmodic atrophy, thereby distinguishing it from atrophy due to other causes; in proved spasmodic cases he gives a daily injection of 2 mg. of atropine. He attributes acute and chronic glaucoma to local vaso-dilatation, and gives daily three doses each of ten drops of 1 in 1,000 adrenaline, one cachet of 20 cg. of ergotine, and two tablespoonfuls of a mixture containing 6.5 per cent. of calcium chloride. He claims good results for this treatment even without the local use of eserine and pilocarpine, and suggests that it would be worth a trial in Ménière's disease, which he considers to be due to a local vaso-dilatation. He believes that the sudden visual eclipses without changes in the fundus, in subjects of hypertension, are due to constriction of cortical arterioles *par passu* with the general condition and not a sequel of it. He records the case of a man, aged 48, healthy except for increased blood pressure, who had two transient attacks of sudden blindness in the left eye; a third attack left him with complete loss of [illegible] in that eye. Ophthalmoscopic examination showed [illegible] in the calibre of the retinal arterioles [illegible] e fundus. Qualitative perception was recovered half an hour after the injection of 1 mg. of atropine into the orbit; the vision continued to improve concurrently with falling of the general blood pressure, under daily injections of 2 mg. of atropine. He attributes the eruptions of frontal herpes to excessive dilatation of arterioles in the course of the supra-orbital artery, in consequence of the action of the herpetic toxin on the sympathetic system, and thinks that the more generalized eruptions of pemphigus are comparable. *Stillmann, W.* [illegible] eated a man suffering from generalized [illegible] eruptions of the skin and mucous mem[illegible] intramuscular injections of 5 c.cm. of a 5 per cent. solution of peptone and intravenous injections of 5 c.cm. of 20 per cent. calcium chloride solution. The eruption was arrested and the patient was ready to leave hospital in eight weeks. Pautrier and Lanzenberg noted the aggravation of a similar condition in a woman, aged 31, who was given an injection of sulfarsenol, which sometimes acts as a vaso-dilator.

687. Hypertonic Salt Solution in Acute Intestinal Obstruction.

E. P. COLEMAN (*Journ. Amer. Med. Assoc.*, April 2nd, 1927, p. 1060) reports good results following the injection of hypertonic saline solution in cases of acute intestinal obstruction. Since the fall in blood chlorides in this condition is closely associated with the toxaemia which is the cause of death, the salt is of great value in combating the toxaemia as well as correcting the chloride deficiency. The 3 per cent. solution is given intravenously or subcutaneously. Coleman reports 38 cases of intestinal obstruction; in 20 of these no hypertonic solution was injected and the patients died. Although the next 18 cases were under similar conditions as regards delay in diagnosis and operative intervention the mortality fell to 11.1 per cent. One quart of saline solution was injected before the operation; the needles were left in position, and one to two quarts were given during the next few hours as clinically indicated. Coleman concludes that the free use of hypertonic salt solution is effective in neutralizing the toxaemia of acute intestinal obstruction, and enables the patient to live for one to three days in spite of the toxaemia, which would probably prove fatal otherwise, even though the obstruction had been relieved.

688. Treatment of Parkinsonism.

L. NEUBERGER (*La Vie Méd.*, April 20th, 1927, p. 593) discusses the pathological processes concerned in Parkinsonism and recommends scopolamine, hyoscine, or hyoscyamine for the treatment of the rigidity and tremors. He gives these alkaloids in coffee and believes that benefit is obtained by the addition of atropine and, possibly, morphine. In some cases belladonna has proved efficacious by itself, but the large doses necessary render its use rather dangerous. Sodium salicylate, in intravenous or intramuscular injections, is often very

valuable in treating the rigidity and painful spasms; more recently it has been given in association with glucose, the daily dose being 60 to 90 grains of the salt in a 10 per cent. solution of glucose in serum. Parathyroid extract has been used alone or in conjunction with stramonium and atropine, and Neuberger suggests that this expensive hormone may be replaced satisfactorily by the cheaper pituitary extract. Other forms of treatment which have been recommended include iodine and malarial therapy. Gardénal has been found effective for the insomnia, and ptyalism, when excessive, has been relieved by deep radiotherapy of the parotid gland. The headache sometimes yields to electrargol. For prolonged treatment Neuberger prefers iodine, either with pepsine or increasing doses of the tincture, followed by periods of smaller dosage, during which stramonium and the salicylates may be given. He emphasizes the importance of re-education by graduated gymnastic exercises.

689. **Sodium Salicylate in Ophthalmology.**

DEFOUG (*Rev. méd. de l'Est*, March 1st, 1927, p. 136) has treated twenty ophthalmological cases of different kinds by intravenous injections of sodium salicylate according to the method introduced by Darier and recently revived by Melville Black. The technique is the same as in the treatment of acute articular rheumatism, lethargic encephalitis, or varicose veins. The injections are given for from five to ten consecutive days in doses of 1 to 2 grams in a 10 to 20 per cent. solution of glucose or normal saline. No cases of subsequent induration of the veins or shock have been observed. In corneal ulcer this method has not proved superior to the ordinary treatment. In irido-cyclitis very variable results have been obtained, the method being applicable to all cases in which antisyphilitic treatment is not obviously indicated. The results were particularly good in wounds of the eyeball with symptoms of irritation, and in sympathetic ophthalmia, as was also found by numerous writers who gave very large doses of salicylate by the mouth.

Disease in Childhood.

690. **Acute Influenzal Meningitis in Infants.**

C. PELFORT (*Arch. de méd. des enf.*, March, 1927, p. 137) states that from December, 1922, to September, 1926, 1,600 children under 3 years of age were admitted to his ward at the Montevideo Children's Hospital. Of these, 26 were suffering from acute purulent meningitis, the pathogenic agent being the meningococcus in 15, Pfeiffer's bacillus in 7, and the pneumococcus in 4. A review of the literature shows that Pfeiffer's bacillus is more frequently responsible for purulent meningitis than is generally supposed, especially in infancy. This is probably the cause of the apparent failure of anti-meningococcal serum in cases regarded as meningococcal in which a careful bacteriological examination had not been made. The clinical appearances are identical with those of purulent meningitis due to other organisms, such as meningococcus, pneumococcus, or streptococcus, and the diagnosis can only be made by bacteriological examination of the cerebro-spinal fluid. The mortality is 100 per cent. Pelfort records seven illustrative cases in children aged from 5 to 19 months, all of which terminated fatally.

691. **Morbid Anatomy of Microcephaly.**

T. BRUSHFIELD and W. WYATT (*Brit. Journ. Child. Dis.*, January–March, 1927, p. 24) allude to their previous paper on microcephalic children (*Epitome*, March 5th, 1927, para. 260) and record their *post mortem* observations on ten cases. In every case there were signs of chronic inflammatory change in the meninges, and the cerebral hemispheres showed a loss of the normal convexity corresponding to the shape of the microcephalic skull. This hypoplasia involved the whole cortex, but was most pronounced in the pariétal and occipital lobes. The presence of small shrunken and misshapen convolutions known as microgyria was found in all. In seven brains there were gross lesions, such as internal hydrocephalus, porencephaly, and developmental anomalies of the corpus callosum. The cerebellum was never affected to the same degree as the cerebrum, but usually appeared comparatively large and well developed. Microscopical examination in one case revealed a remarkable increase of the Purkinje cells. The spinal cord was abnormally thin and underdeveloped, the pyramidal tracts being especially affected. Microscopically the cerebral cortex showed a definite paucity of neurones, while of those present many showed immaturity, imperfect development, or signs of degeneration and irregular arrangement. The conclusion drawn from examination of the brains was that the underlying cause was at work before birth. Whatever the lesion in the cerebral hemispheres the result was the same—namely, the destruction of the upper neurones of the pyramidal tract. The unopposed influence of impulses from the extrapyramidal tracts and probably from the cerebellum also explained the clinical features of paresis and rigidity.

692. **Acute Leukaemia in Children.**

P. JEULIN (*Thèse de Paris*, 1926, No. 572), who records sixteen cases in patients aged from 6 months to 18 years, states that acute leukaemia is a rare affection in childhood, though the most frequent form of leukaemia observed at this period of life. The symptoms of acute leukaemia in children are similar to those in the adult, except that apart from fever and anaemia the clinical picture is hardly ever complete. The presence in the blood of undifferentiated cells is the pathognomonic sign of acute leukaemia, and next in importance come diminution in the number of red cells and a leucocytosis of moderate intensity. It is sometimes very difficult to diagnose between acute leukaemia and infantile anaemia, as very subtle transitions and associations may exist between these different conditions. The etiology is still obscure and no treatment has yet been found of any avail.

693. **Injuries of the Spinal Cord in the Newborn.**

B. CROTHERS and MARIAN C. PUTNAM (*Medicine*, February, 1927, p. 41) consider that in many cases of paralysis of the arm due to lateral traction on the brachial plexus during birth signs of injury to the cord are also present. They believe that any part of the nervous system may be injured by accidents during delivery, and that rupture of tissues may follow undue stress upon any part of the foetus, resulting in a variety of physiological disturbances rather than in clearly defined syndromes. Notes of twenty-eight cases are given, together with several from the literature indicating the importance of obstetrical injury to the spinal cord as a cause of disability; the possibility of its occurrence should be considered whenever signs suggestive of a diffuse, non-selective, and fixed lesion of the cord are present. Though the authors' patients exhibited no discrete syndromes, some showed flaccid paraplegia, apparently due to almost complete destruction of the lower cord; in others there were active reflexes dependent upon the isolated part of the transected cord, and some presented disturbances due to perverted control as a result of partial destruction of afferent or efferent tracts. In nearly every case the injuries followed the application of traction during delivery, and there seemed no valid reason for concluding that asphyxia or generalized pressure was responsible for the atypical cases. The authors consider that in obstetrical teaching there is need of increased emphasis upon the methods of avoiding injury and less attention to asphyxia.

Obstetrics and Gynaecology.

695. **Induction of Labour for Foetal Post-maturity.**

K. ADLER (*Zentralbl. f. Gynäk.*, April 23rd, 1927, p. 1049) quotes as evidence of the danger to foetus and mother which accompanies protracted gestation (1) Ruge's observation that stillbirth is almost invariable after pregnancy exceeding 302 days, (2) the finding of Zangemeister and Lehn that operative delivery is twice as frequently necessary in children whose weight is over 4½ kilograms as in others, and (3) Stoeckel's report of foetal mortalities of 3.5, 10.5, and 85 per cent. in infants weighing respectively from 4 to 4½ kilograms, from 4½ to 6 kilograms, and over 6 kilograms. For the induction of labour for foetal post-maturity the following means have been proposed: (1) Introduction of small dilating bags; these are effective, but there is a certain danger, apart from that of infection, of premature rupture of the membranes or prolapse of the umbilical cord or small parts. (2) Rupture of the membranes combined with parenteral injections of quinine or pituitary extract. (3) Mechanical stimulation of the uterus by a vibration apparatus. In using any of these methods Adler states that it must be remembered that a correct judgement as to foetal maturity is often extremely difficult; they are all fraught with the disadvantage that if they are effective termination of labour is certain and irrevocable. Accordingly he prefers the method of Stein of New York, who advises oral administration of castor oil and injection of pituitary extract. In common with other observers he has found that this method, while effective in a high percentage of cases, is entirely without effect on the uterus in patients who have not reached term. Adler gives one or two tablespoonfuls of castor oil in the morning, followed when intestinal peristalsis is noted—usually after two hours—by intramuscular injections of pituitary extract; three further injections are given at half-hour intervals. In the majority of successful cases uterine pains begin in about two hours. This method of induction was successful in 61 out of 100 cases;

in 4 out of 5 of the successful cases a portion at least of the foetal head lay in the pelvis before treatment, while in two-thirds of the unsuccessful cases the head had not entered the pelvis. In the successful cases the length of the foetus was between 48 and 57 cm. and the weight from 3.12 to 4.58 kg. Premature rupture of the membranes occurred in 8.2 per cent. of the successful cases. In 10 patients castor oil and pituitary extract were not effective until a second or third injection. The author adds that the method is not likely to prove useful in cases of contracted pelvis, in which entry of the presenting part is slow.

695. Sarcomatous Degeneration of a Uterine Fibroid.

R. SCHOCKAERT (*Bruxelles Méd.*, May 22nd, 1927, p. 959) describes the case of an unmarried woman, aged 79, admitted to hospital on account of a blood-stained and slightly offensive vaginal discharge which had begun suddenly four weeks previously. Her menstrual history had been quite normal and the menopause had occurred without trouble at the age of 49. When she was 46 years of age there had been some retention of urine, probably due to pressure by a fibroid. Bimanual examination revealed a normal cervix slightly deviated to the right, and a number of uterine fibromata were felt. Total hysterectomy was performed under spinal anaesthesia, and examination of the specimen showed two pedunculated and two sessile subserous fibromas, each about the size of an orange, and between them another tumour of softer consistency which had perforated the mucous membrane of the uterus and protruded through it in the form of a polypus; histological examination showed that this last was sarcomatous. The patient passed through the operation well in spite of her age. Commenting on the advantages of spinal anaesthesia in such cases Schockaert pleads for more careful supervision, even after the menopause, of patients known to have uterine fibroids; he thinks that operative treatment might be employed more often. Surgical intervention would obviate the relatively rare risk of malignant degeneration in the tumours and also the dangers and discomfort attending simple cystic changes, which may come on with great rapidity at any age.

696. Radium Treatment of Haemorrhagic Metropathy.

C. A. CASTAÑO (*Gynécol. et Obstét.*, March, 1927, p. 196) regards it as proved that excessive uterine haemorrhage, in the absence of gross organic disease of the uterus or adnexa (metropathica haemorrhagica, ovariopathic haemorrhage), is due to the excessive production of a hormone in the ovary, whether by persistence of corpora lutea, excessive richness in lipoids, or the presence of special cells of an interstitial gland. It has been generally conceded that the success of radium application in arresting the bleeding in these cases is due chiefly to the irradiation of the ovaries; Castaño claims that by small dosage it is possible, nevertheless, to conserve the normal functioning of the Graafian follicles, and thus to avoid interference with menstruation and reproduction. He records the cases of three patients, of whom two were sterile, who had had ovariopathic haemorrhage, refractory to treatment, for eight years, two years, and eleven years respectively. One patient, two years after radium applications, gave birth at term to a living well formed healthy foetus weighing 4 kg. Another aborted at the sixth month, having become pregnant six months after radium application; this patient, who suffered from hereditary syphilis, had sclerosis of the cervix uteri, attributable to radium. A third patient, who was also syphilitic, had normal menstruation for twelve months after radium applications, when she became pregnant and gave birth to a living child at term. A second pregnancy occurred three years later, but ended in abortion after a severe biliary infection. Castaño gives two radium applications at a few weeks' interval.

Pathology.

697. Etiology of Erythraemia.

V. TRAMONTANO (*Rass. Int. Clin. Ter.*, March, 1927, p. 154) gives a detailed account of the clinical findings and complicating symptoms met with in erythraemia, which he illustrates by a typical case. He discusses the different views of its etiology and states that by most authors it is considered to be a primary hyperplasia of the erythroblastic and myeloid tissue due to some as yet unknown morbid stimulus. Another view, that it is a secondary compensating reaction, is based on the assertion that the power of oxygen fixation by the haemoglobin in these cases is markedly less than in healthy persons; this statement, however, is not always confirmed by observation. Whereas some have described the condition as an erythroblastoma or primitive hyperplasia of the erythroblastic system, by others it is regarded as an erythrocytosis due to idiopathic hyperfunctioning of the erythroblastic apparatus through stimulating agents acting directly on the bone marrow, in contrast with the erythrocytosis of high altitudes and of diseases of the heart and lungs, which are produced by indirect action on the bone marrow. *Post-mortem* findings in cases of erythraemia confirm the existence of hyperplasia of the bone marrow, and the extension of the myeloid tissue to situations where it is not usually met with in normal adults. The disease has been attributed to acute infections, to chronic infections such as malaria, syphilis, and tubercle, to intestinal intoxication, to trauma, and also to endocrine defects. Tramontano has collected some evidence to show that the condition appears in families and may be inherited; it may remain latent until, through some known or accidental cause, it is manifested as a severe progressive disease.

698. Estimation of Chlorides in Blood and Urine.

S. L. LEIBOFF (*Journ. Lab. and Clin. Med.*, April, 1927, p. 702) describes a rapid method of estimating the chloride content of blood or urine. It consists in neutralizing the chloride-containing solution with calcium carbonate and titrating it with silver nitrate; sodium chromate is used as an indicator, and a red colour appears when all the chlorine has been precipitated from the solution. For a blood test 5 c.cm. of the tungstic acid filtrate, obtained by the Folin-Wu method from half a gram of blood, is placed in a small beaker, 5 c.cm. of water in a similar beaker being used as a control. To each beaker 0.3 gram of powdered calcium carbonate is added, together with 0.5 c.cm. of the sodium chromate indicator. One drop of the standard silver nitrate solution in a burette is run into the control, after which this solution is dropped slowly into the blood filtrate until the colour is similar to that in the control. The calculation of the chloride content is simple. In testing urine 5 c.cm. of urine is used as the control. Leiboff has compared this method with others and finds it accurate.

699. The Suspension Stability in Pulmonary Tuberculosis.

O. STUB (*Norsk Mag. f. Laegevid.*, April, 1927, p. 233) examined the suspension stability of the blood in pulmonary tuberculosis according to Westergreen's method; 1,171 examinations in all were made, 550 on 383 men and 621 on 426 women. His conclusions are as follows. There is a close association between the different stages of the disease according to Turban-Gerhardt and the results of the reaction, the greatest reduction of stability being noted in the third stage and the least in the first. In the course of each of the stages feverish patients and those with bacilli in their sputum show a greater reduction of stability than the rest. The stage of the illness and the presence of bacilli are of greater influence on the reaction than a rise of temperature. The test is therefore of some value in determining the activity of the disease. As regards the result of treatment on the sedimentation rate in those who derived benefit from the employment of sanocrysin or artificial pneumothorax, the stability reaction showed a decided tendency to fall, but rose again quickly in cases complicated by pleurisy.

700. The Basal Metabolism in Diabetes.

L. HÉDON (*Paris Méd.*, May 7th, 1927, p. 446) asserts that estimation of the basal metabolism is as useful in diabetes, as regards prognosis and the control of treatment, as in thyroid troubles. Opinions differ whether in diabetes the basal metabolism is diminished, increased, or normal. These differences are probably due to varying standards of normal metabolism, which is affected also by diet and acidosis. Hédon believes that in diabetic patients who are not very emaciated, and who are living on a diet poor in carbohydrates but rich in proteins and fats, the basal metabolism is increased, sometimes by as much as 30 per cent.; he suggests that the degree of increase may be a measure of the gravity of the disease. In markedly emaciated diabetics two conditions arise: if the diet is as above basal metabolism is greatly increased, but if the patients are subjected to fasting and then to a low diet it is markedly decreased, at times as much as 40 per cent. Depancreatized dogs show an increased basal metabolism of about 30 per cent. In these dogs with this increased metabolism the administration of insulin does not at first affect the increase. After prolonged treatment and a carbohydrate diet the animals recover their health and weight, and the metabolism becomes normal. If insulin is then stopped the basal metabolism again increases by 30 per cent. and diabetes reappears. Hédon maintains that if the basal metabolism is really increased in diabetics insulin ought, as in the depancreatized dog, to restore it to normal. The increase may be due to a faulty economy of combustion. If partly or wholly compensated by the action of insulin the increase may be due to diminution or absence of the internal pancreatic secretion.

CURRENT NOTES.

Gift to the Association of a Bust of Hippocrates.

A bust of Hippocrates, the work of Mr. Aumonier, and the gift of the publishing firm of Messrs. H. K. Lewis and Co., Ltd., of Gower Street, has been placed in the members' Common Room at the Association's House. What the features of the Father of Medicine were like is not, of course, known, but the sculptor has managed to convey the suggestion of sagacity and humanity, and the work recalls busts of the great contemporaries of Hippocrates—Aeschylus and Sophocles—in the Italian galleries. It is mounted on a suitable bracket, with a scroll quoting from the famous Oath.

The bust was unveiled by Mr. H. L. Jackson, chairman of the board of directors of Messrs. Lewis, in the presence of members of the Council and others, on December 15th. Mr. Jackson said that he wished to acknowledge the sympathetic way in which the Council had responded to the suggestion of his firm that it might be permitted to make some gesture of neighbourliness on the Association's settlement in the interesting district of Bloomsbury. The Association was twelve years older than his firm. He was not sure how soon after 1844 business relations between them began, but when he himself went to Gower Street in 1888 they were of long standing. He believed the Association counted upon its fine premises as its home for a period running into centuries; whether Lewis's would continue in Gower Street for so long a time it was not for him to say. No one could tell how methods of book production and distribution might be revolutionized. But while the present organization existed he hoped the same ideal of service would remain. Mr. Jackson added that a growing experience had impressed him with a sense of the great ideals which prevailed in the medical profession. A publisher had perhaps exceptional opportunities of seeing what was really being aimed at. Authors were often quaintly self-revealing. It was rather sad to think how many times the Thames—of the medical world—would have been set on fire had it not been for the cold obstruction of some unimaginative publisher. (Laughter.) If an author were asked to indicate a pessimist he would probably point out someone in the publishing business. It was not for him to offer in that company any remarks on the Hippocratic method, though he noticed that the great physician of Cos was said to have attached considerable importance to diet and exercise. Hippocrates, however, did not have the doubtful advantage of a daily press in which to circulate his opinions. Mr. Jackson then, amid applause, unveiled the bust.

Sir Robert Bolam expressed the Council's pleasure in accepting this fine work of art. The name of Lewis was a household word in the medical profession, and he trusted that the business connexion which had existed for so long and had always been so pleasant would continue indefinitely. He mentioned that Mr. Jackson had brought with him five colleagues who together represented something like 200 years' service with his firm. The bust would be a dignified addition to the ornamentation of the House, and he hoped the sight of it would be an inspiration, especially to the younger members of the profession, to follow in the worthy traditions of the past.

Poor Law Medical Attendance in Guernsey.

There has recently been trouble in the area of the Guernsey and Alderney Division in regard to the attendance on Poor Law cases in the island of Guernsey. It seems that the Central Poor Law Board was anxious to reorganize the service with a view to economy. This led to a proposal to cut down the districts from eight to four or five. Representatives of the Guernsey and Alderney Division met the Central Board on two occasions and laid their views before it. The Division maintained that the new arrangement would be neither economical nor efficient. The district medical officers stated that they were prepared to do the work at the rate of 7s. 6d. a visit and 2s. 6d. for consultation and medicine, or to continue for a further year under the existing scheme, in order that during that time definite figures as to the amount of work involved might be obtained. Things have now come to a head. The Central Poor Law Board has not accepted the doctors' views, but has cut down the number of districts to five, and this has entailed in some cases a reduction of the salaries which were previously paid, in other cases the salary remaining the same as before. It is hoped that the medical profession at large will support the action taken by the Division by not applying for the posts which have been rendered vacant, and that, if any practitioners have applied before seeing this note, they will withdraw their applications without delay.

PROCEEDINGS OF COUNCIL.

Wednesday and Thursday, December 15th and 16th, 1926.

A MEETING of the Council was held at the House of the Association, Tavistock Square, on Wednesday, December 15th, from 10 a.m. until 6.45 p.m., and again on the following day, from 10 a.m. until 4 p.m. Sir ROBERT BOLAM was in the chair, and the members present were:

Mr. R. G. Hogarth (President), Dr. H. B. Brackenbury (Chairman of Representative Body), Mr. N. Bishop, Dr. C. O. Hawthorne (Deputy Chairman of Council), Dr. J. Barcroft Anderson, Surgeon Rear-Adm. [illegible] Smith, Dr. H. S. Beadles, Major General Sir [illegible] Buchan, Dr. H. G. J. W. Bone, Dr. H. C. Dain, Dr. J. S. Darling, *Mr. T. P. Dunhill, Mr. W. McAdam Eccles, Dr. F. J. Gomez, Dr. D. G. Greenfield, Dr. R. Wallace Henry, Dr. G. B. Hillman, Dr. J. Hudson, Dr. I. W. Johnson, Dr. R. Langdon-Down, Dr. David Lawson, Dr. E. K. Le Fleming, Dr. R. W. Leslie, Dr. E. Lewys-Lloyd, Sir Richard Luce, M.P., Dr. A. Lyndon, *Dr. R. A. Lyster, Dr. J. G. McCutcheon, Dr. S. Morton Mackenzie, Dr. A. Manknell, Dr. O. Marriott, Dr. J. C. Matthews, *Dr. G. W. Miller, Dr. Hugh Miller, Dr. Christine Murrell, *Lieut.-Colonel F. O'Kinealy, Dr. W. Paterson, Dr. J. Dodds Price, Dr. F. Radcliffe, *Mr. H. S. Souttar, *Dr. Lockhart Stephens, Dr. John Stevens, *Dr. W. E. Thomas, Dr. G. Clark Trotter, Mr. E. B. Turner, Sir Jenner Verrall, Dr. J. F. Walker, Sir William de Courcy Wheeler.

* Not present at meeting on December 16th, 1926.

Apologies for absence were received from Dr. F. G. Thomson (Past President), Sir Robert Philip (President-Elect), Dr. G. A. Allan, Dr. T. Ridley Bailey, Dr. D. E. Finlay, Dr. J. A. Macdonald, Dr. John Mills, Mr. A. W. Nuthall, Group Captain N. J. Roche, and Dr. D. Walshe.

The Chairman mentioned that Dr. Ridley Bailey, who had sent an apology for absence, was gravely ill in a nursing home following an operation. He knew that Dr. Bailey would value a message of sympathy from the Council more than almost anything else. The Council signified its desire that such a message should be immediately sent.

The Chairman also remarked with regret the absence of Dr. J. A. Macdonald. In his case, happily, there was no serious illness, but he had been ordered to take a rest and holiday.

President of the Association, 1928-29.

Following upon a formal nomination by the Cardiff Division, the Council agreed, on the motion of the Chairman, to recommend to the Representative Body that Professor Sir Ewen J. Maclean, M.D., F.R.C.P., be elected President of the Association, 1928-29.

Special Committee on Psycho-Analysis.

The Council at its previous meeting agreed to set up a special committee to consider the whole position of psycho-analysis in medicine. Certain names were now submitted as those of persons suitable to act on such a committee. It was stated that in no case had it been ascertained whether these were willing to serve, and the Chairman remarked that some of them had been members of a committee with a similar reference appointed by another body of importance which failed to arrive at any conclusion, and possibly might not be disposed to try again.

The Council, after discussion, decided to add several names to those suggested, including one woman member, but did not agree with a proposal that it should appoint a chairman, leaving that duty to the committee itself.

Representatives of Association on Outside Bodies.

Sir Robert Bolam was reappointed representative of the Association on the court of governors of the London School of Hygiene and Tropical Medicine. Dr. Hawthorne was asked to represent the Association on a small advisory committee of clinical experts to consider the details of the proposed alterations suggested by the British Government at the forthcoming revision of the international list of causes of death, by the Health Section of the League of Nations. Mr. E. B. Turner and Dr. Garstang, who had served for some years as representatives on the Central Council for District Nursing in London, did not wish to be reappointed, and in their stead Mr. Comyns Berkeley and Dr. Howard Stratford were nominated, together with Dr. W. Paterson, who had served previously and was willing to continue. A vote of thanks was accorded to Mr. Turner and Dr. Garstang for their services. Dr. Hillman and Dr. Lyndon were reappointed representatives on the Joint Tuberculosis Council; Dr. Buchan and Dr. Johnson were asked to act as delegates at the annual congress of the Royal Sanitary Institute in July, and Dr. Buchan, Mr. Souttar, Sir Jenner Verrall, and the Deputy Medical Secretary were appointed delegates to the conference representative of all interested in the nursing profession, summoned by the Labour party for January 28th. The Royal Society is organizing a celebration in London of the Lister centenary, and the Council nominated as its delegate the President of the Association.

The Chairman reported that, in pursuance of the resolution of the Council, a certain number of shares in the Scholastic, Clerical, and Medical Association, Limited, had been purchased.

Pathological Laboratories and Private Practitioners of Pathology.

Dr. Hawthorne presented a report of the Pathological Committee which was appointed to consider the question of the exploitation, for the purposes of commercial advertisement, of routine clinical pathological work, and the publication in the JOURNAL of advertisements of laboratories in so far as these might be considered to affect the interests of the private practitioner of pathology. The report was a lengthy document; its drift may be gathered from the recommendations which the Council discussed one by one. Dr. Hawthorne read several letters from teachers of pathology in the leading medical schools expressing practically unanimous and in some cases enthusiastic support for the committee's findings. The principles underlying the report, he said, might be stated in two propositions: (1) that clinical pathology was a special expert department of medical practice and ought to enjoy the status and to be governed by the customs and regulations which applied to other specialized departments of practice; (2) that the value of clinical pathology in the individual case was heightened when the facts as found rested upon a personal guarantee. The committee had also recognized two special dangers in clinical pathology as at present existing: (1) that the practice might come to be dominated by commercial considerations, and (2) that it might be separated from the main stream of medical practice. The committee laid considerable stress upon the main body of its report, which it presented to the Council in the hope that it would prove a useful instrument for the benefit of the pathologist and of the whole profession. He then moved the first recommendation, which read:

> That the Council disapproves of the establishment by commercial firms of laboratories offering pathological examinations and reports on individual cases, and advises members of the Association to avoid any association with such enterprises; the Council also directs that advertisements of such organizations be not admitted to the BRITISH MEDICAL JOURNAL.

Dr. Hawthorne said that it was well known that certain commercial firms had established laboratories where they received specimens and issued reports on individual cases, and cheap fees were charged. If it was right and proper for a commercial firm, for its own ends, to offer cheap facilities for clinical pathology, there would seem to be no objection to the firm setting up, for example, a cheap x-ray department, or even arranging for the consultant services of physicians or surgeons.

Dr. Fothergill desired that this and the other recommendations should be submitted to the Representative Meeting. Dr. Hawthorne replied that that was for the Council to say. A point to be taken into account was that the clinical pathologists in the country were beginning to associate themselves together, and were likely soon to voice their wishes and ambitions in some collective form. Therefore he suggested that the Council should pass the recommendations as they stood, and leave it to the next meeting to decide whether they should go to the Representative Meeting, because it was just possible that in the meantime something might be heard from clinical pathologists as a corporate body which would suggest the desirability of certain modifications in the form, though not in the principle, of the recommendations.

Dr. Fothergill considered this to be an argument for adjourning the whole question, but Dr. Hawthorne hoped the matter

would proceed; this was the deliberate judgement of his committee, and owing to the pressure of other business at the previous meeting of the Council the consideration of the report had already been delayed beyond the time expected.

The Chairman said that certain parts of the recommendations were obviously matters for the Council, though the action of the Council must be conditioned by some general principles, such as the one set out at the beginning of this first recommendation.

Dr. Brackenbury was of opinion that the Council should take some definite action that day. The committee had spent a large amount of time on this matter, and had brought forward certain conclusions for the Council's endorsement. The whole subject was so important that in his opinion it certainly ought to go before the Representative Meeting, but the Council should now decide on these recommendations, even though the form of them might have to be modified. If any representative members of the profession interested in these matters held a conference that would be all to the good. Any action suggested in these recommendations would, of course, be postponed until the Representative Meeting had expressed its view.

Dr. Bone raised the question of a particular research body, which could hardly be described as a commercial firm. Did Dr. Hawthorne consider that there was any exploitation of pathologists by that body? The Chairman said that what the committee had in mind was, not the setting up of laboratories by people with a commercial intention who ran the laboratory by itself, but the running of a laboratory in association with other commercial business which it was the purpose of the laboratory to advertise. He was not at all sure that it was undesirable in some instances to enlist the support of commercial people in running laboratories under proper conditions. Dr. Hawthorne said that the organization to which Dr. Bone referred existed solely for its laboratories, the laboratories could not be described as a side-line to some other commercial enterprise, and therefore it did not come within the sphere of this recommendation. Dr. Bone thought, nevertheless, that the case of a commercial company of laymen employing the services of pathologists was one that should have the committee's attention.

It was eventually suggested that the wording of the recommendation should be altered to read, "That the Council disapproves of the establishment by trading firms of laboratories as subsidiary enterprises for the purpose of offering pathological examinations," etc., and in this form it was agreed to.

Mr. McAdam Eccles asked what would be the position of a member of the Association engaged in such a laboratory. Dr. Hawthorne said that it would be unjust to give it a retrospective effect. Nor would the status of a member who took up such a position in the future be affected unless someone brought forward a specific charge of improper conduct against him. Certainly it would not alter the status of any individual hitherto employed.

The second recommendation ran:

> That the Council directs that only those advertisements of pathological institutions and laboratories be accepted for insertion in the BRITISH MEDICAL JOURNAL which conform to the following conditions:
>
> (i) That the offer of the advertisement is accompanied by a guarantee from some responsible person that the work of the laboratory is conducted by a registered medical practitioner;
>
> (ii) that the name of this practitioner must appear with the advertisement; and
>
> (iii) that the advertisement quotes no tariff or fees, and includes no names of preparations offered for sale and no descriptions of special or particular kinds of work conducted at the laboratory.

Dr. Hawthorne said that it was at first proposed that advertisements of these institutions should be excluded, but it was recognized that there were parts of the country where the private pathologist was almost unknown and inaccessible, and therefore that it must be for the convenience of practitioners in those districts to know of organizations where they could get their reports.

Dr. Fothergill desired the Council to adjourn consideration of this recommendation until the Ethical Committee had reported on it. There was some risk that by laying down these conditions the Council should imply an approval of "covering." Dr. Manknell seconded, on a different ground, that if these institutions were allowed to advertise in the JOURNAL they did so at the expense of the private pathologist, who could not advertise. Dr. Brackenbury pointed out that the Council deliberately set up a special committee on this whole subject because it did not wish, by sending it to one of the standing committees, to give the matter a sectional bias. But the Ethical Committee, like the Medico-Political and the Journal Committees, had its representatives on this committee.

Dr. Fothergill's motion was lost, and Dr. Bone then moved to refer back the recommendation on the ground that the conditions set out were not sufficient to attain the objects which should be kept in view. An institution might fulfil every one of the conditions set out in the recommendation, and yet its pathologist might be exploited by a limited liability company of laymen making large profits from the work of scientific men.

Mr. Souttar thought the Council was in some danger of confusing the employment of medical men by laymen and the exploitation of medical men by laymen. It was quite possible, and he thought probable, that in certain bodies medical men were employed to their benefit. Surely it was a good thing that a body of laymen, under proper conditions, should employ medical men. It had been considered better that medical men themselves should not engage in the management of business concerns. In the near future large nursing institutions would be formed for private patients, corresponding to the hospitals, and considerations of this sort would enter very largely.

Dr. Brackenbury said that if conditions other than those set out in the recommendation were applied to pathological institutes there would be great difficulty in not applying them to institutions of other kinds, such as hydropathic and nursing institutions, which were also run by laymen and employed medical men.

Dr. Lawson thought the committee had got out of its depth. The future advance of medicine was in team work, which could only be effectively done in institutions having large capital; this capital must be put up by laymen, who would expect a dividend. It was no concern of the Pathological Committee or anybody else what return these people got for their invested capital, provided they paid adequate salaries to the doctors and pathologists they employed.

Dr. Hawthorne said he took it for granted that the Council would permit such advertisements, and that being the case it remained to discuss the conditions on which they should be accepted. He was not very keen personally on some of the conditions, but the name should be insisted on as a guarantee. The objection to the insertion of fees or tariff was that it might lead to the very undignified procedure of fee-cutting. As to descriptions, the type of work done in any institution would be sufficiently indicated by its title. If other descriptions were allowed such statements might appear as "Blood-sugar testing a specialty," and one institution would endeavour to outbid others.

The motion to refer back was lost. It was agreed, on the motion of Sir Jenner Verrall, seconded by Mr. Souttar, to delete the requirement that the name of the practitioner must appear with the advertisement, and to add the words "whose name shall be supplied to the office" at the end of subparagraph (i). Mr. Souttar further proposed, and Dr. Bristowe seconded, the deletion of all words after "fees" in subparagraph (iii). Dr. Hawthorne said that he could not accept this deletion. It was a very important part of the proposals that the advertisement should not include preparations for sale. Dr. Brackenbury said that the purpose of this provision was to protect the private pathologist, whose point of view must be remembered. The Chairman did not see how the institution could well be prevented from advertising such things as stock vaccines. Mr. Souttar's proposition was carried, and the recommendation as amended was then agreed to.

Dr. Hawthorne, in bringing forward the third recommendation—

> That in the opinion of the Council all institutions undertaking pathological examinations and reports should include in any intimation made to the profession the name of the registered medical practitioner in charge of the laboratory, and that each report issued from the laboratory should be guaranteed by the personal signature in writing either of this practitioner or of some other registered medical practitioner approved by him—

said that the private pathologist naturally objected to the invasion of the particular district in which he practised by advertisements from central institutions. Owing to established custom, and to the fact that there were parts of the country

where the services of a private pathologist were not available, these intimations could not be stopped altogether, but it was thought that they might be subject to the conditions laid down.

The recommendation was agreed to.

The fourth recommendation ran :

> That the Council records its disapproval of any arrangements whereby the governing body of a hospital or medical school, as such, professes to organize and to advertise a pathological institute for general service.

Dr. Douglas hoped that this would not be passed straight away. In Scotland there was a fully organized system which was almost exactly that disapproved of in the recommendation. The work of pathological examination in Scotland was done almost entirely by its medical schools and universities, and Scotland would be placed in an awkward and invidious position if this recommendation were passed. He added, in reply to Dr. Hawthorne, that there was no advertisement of these bodies, but it was a thing understood by all the local authorities and others that they would do the work. Dr. Brackenbury said that an arrangement between a public authority and a medical school would not come under the ban of the recommendation.

Dr. Radcliffe and Dr. Fothergill also deprecated the terms of the recommendation, and described the conditions obtaining in relation to general hospitals in their areas. The President said that it had been a custom for certain hospitals to appoint pathologists who, in addition to their salaried hospital work, were allowed to do pathological work for other doctors. These doctors were notified that they could send their work to the pathological laboratory at the hospital, and for this the pathologists received additional remuneration. Dr. Lyndon said that St. Bartholomew's had had a clinical research department for over twenty years, and advertised it, at least in the hospital journal.

Dr. Hawthorne pointed out that to come under the ban of this recommendation the laboratory must be organized for general service and must be advertised. The Association had always been anxious to protect private practice from the unfair competition of hospitals, and surely it should extend that protection to private practitioners of pathology. He could not say how this would affect one particular institution, but if there was no public advertisement issued from the hospital there would be no ground for quarrel.

The Chairman, speaking as a private member, said that he had had some personal experience of this class of work, and he thought the recommendation was an example of legislation framed to meet one particular case without sufficient regard to circumstances elsewhere. It was quite conceivable that in London an arrangement might be mischievous which was nevertheless a necessary arrangement in other parts of the country. In London there was a possibility for a private clinical pathologist getting a living, but in a provincial area it was unlikely that he would get enough work to support him, and having regard to this fact local authorities already had contracted for the routine work to be done in medical schools and universities or in some cases had set up their own laboratories. Thus a considerable amount of work had been allocated, and would never come back to the private pathologist, because he could not do it economically enough to hold the market. The recommendation seemed to make it illegal to do what the schools had done for many years, not only in public health, but also—at least in the northern counties—in the way of general service, furnishing a guarantee to the profession that there was a pathologist of repute available.

Dr. Hawthorne said the committee had based its finding on a sound general principle. There was no objection to any of these institutions having a properly skilled pathologist, but his committee had felt that that pathologist ought to be allowed to practise as a private pathologist in the same way as a physician or surgeon at the hospital was allowed to practise. If by some arrangement he was allowed to do private work at the institution there was no wish to interfere with that at all, but the speaker did not follow Sir Robert Bolam's argument that to attempt to practise as a private pathologist was hopeless, and that everything must be under an institutional scheme.

After some further discussion the recommendation was lost.

In moving the final recommendation—

> That in the opinion of the Council public health authorities should not furnish pathological reports on individual cases except (i) in cases which directly involve questions of public health, or (ii) where the patient is unable to pay a fee, or (iii) where provision is made for such reports by statutory right—

Dr. Hawthorne said that this was an endeavour to define the pathological work that could be properly undertaken by public bodies. It had arisen from a complaint by the South Staffordshire Division about an intimation to medical practitioners from the Staffordshire County Council that free pathological examinations over a wide field could be obtained at the council's laboratory, and this for rich and poor alike. The county laboratory, however, had issued a further circular letter to the profession defining more clearly its activities as relating only to public health matters, and this was held by the committee to meet the objections raised by the local profession.

Dr. Fothergill moved that the recommendation be referred back, on account of vague and unsatisfactory wording.

The Chairman drew attention to a case reported by the Public Health Committee of the Association. It was proposed that a municipal laboratory be installed in Plymouth, with a whole-time pathologist, and that, in the words of the medical officer of health for Plymouth, "local authorities, farmers, and others throughout Cornwall and the west of Devon would send their specimens to our laboratory, and pay to the corporation the appropriate fees for these examinations." Dr. Brackenbury said that so far as the actual medical work of this proposed laboratory was concerned, it would appear to comply with the provisions of the recommendation. But it was an up-to-date illustration of the problem with which they were faced, that it was proposed increasingly to establish laboratories on these lines, and in this case it proposed to cover a wide area of country.

Dr. Lyster opposed the recommendation. He said that some local authorities had found it impossible to make arrangements with hospitals or universities, and had been compelled to form their own pathological laboratory, which was run to the great convenience and benefit of practitioners.

The Chairman suggested that the phrase "in general" should be placed in the forefront of the proposal. Dr. Hawthorne said that if this were done all the finality would be taken out of it. If the Council thought the right course was to discourage private practitioners from becoming pathological experts, and to encourage these institutions *en masse*, it would dismiss this recommendation. But it would be a strange thing in the Association to hear that the Council believed in the encouragement of public institutions and discriminated against the private practitioner.

The recommendation was agreed to by a large majority. The Chairman remarked that there was nothing in this to prevent a pathologist employed by a local authority engaging, if the institution permitted him, in work for persons outside who would pay for such work.

On the motion for general approval of the report, Dr. Fothergill moved to amend one of the general propositions, which read : "In no circumstances should a pathological report be furnished to any person other than a qualified medical practitioner." Dr. Fothergill desired that it should read : "That a pathological report should not be given to any person other than to a registered medical practitioner unless the consent of such practitioner has been first obtained." Dr. Hawthorne expressed his willingness to modify the wording somewhat in this sense, but Dr. Brackenbury and Mr. Bishop Harman, members of the committee, objected, Dr. Brackenbury again urging the importance of preserving the relationship between the private doctor and his patient, and Dr. Hawthorne then withdrew his acceptance, and Dr. Fothergill's amendment was voted on and lost.

Dr. Fothergill also proposed a variation in another section of the report dealing with the utilization by private practitioners of the laboratories of hospitals and medical schools as a source of information. The words he proposed were :

> Whilst the pathologist by a financial arrangement with the governing authority may utilize the resources of the laboratory for personal practice it is desirable that the fees for examination made for non-hospital patients should be paid to the pathologist.

Dr. Hawthorne said that if the pathologist and the governing body of the institution came to an arrangement by which the pathologist paid an annual sum for the use of the facilities of the hospital for his private practice, the arrangement was one to which they would have no objection, but the fees for examining individual specimens ought to be the property of the

pathologist. Whatever might be the financial arrangement, the fees should go to the individual man who did the work.

The Chairman said that the arrangement which a good many hospitals and medical schools had was that a small percentage—usually only a nominal amount—was paid on every individual fee to the university or school, and in return for that arrangement the institution undertook the trouble and responsibility of collecting the fees. This arrangement, in his own experience in the north, had been quite satisfactory.

Dr. Brackenbury said that what the committee urged was that if a pathologist employed by a hospital, medical school, or public authority was allowed to do private work he ought to receive the emoluments for such work. In many areas the private pathologist, without the anchorage of an institution, would be unable to earn a living.

Dr. Dain was afraid lest the Council should do something which was "grandmotherly." Would it not be better to leave the arrangements to the pathologist and the institution?

Mr. Bishop Harman said that it amazed him to hear the representative of Birmingham, the champion of collective bargaining, pleading that every man should do what was right in his own eyes! To leave the matter at a loose end would be to let down some of the hardest worked and least recognized men in the profession.

Dr. Brackenbury suggested that to meet the point the following be made an additional recommendation:

> That where a pathologist attached to a hospital or medical school undertaking pathological work as a general service does such work for persons able to pay fees, the fees paid for such work should be the property of the pathologist, subject to such charge for the use of the laboratory as may be arranged.

He was anxious not to leave unsafeguarded the people out of whose case the reference to the committee arose.

Dr. Fothergill withdrew his amendment in favour of Dr. Brackenbury's form of words; Dr. Hawthorne also accepted it, and it was agreed to. It was also agreed that the report and recommendations should go to the Representative Body, and that no effect be given in the matter of advertisements in the BRITISH MEDICAL JOURNAL pending consideration by the Representative Body.

Medical Officers of Public Schools.

Dr. Bone (chairman, Medico-Political Committee) reported that his committee, in conjunction with representatives of medical officers of public schools, had considered the question of the duties and remuneration of whole-time and part-time medical officers of public schools, with a view to improvement and co-ordination. The committee had adopted a memorandum drawn up by the school medical officers which, it considered, would assist both the Council and the Representative Body in appreciating the difficulties peculiar to the post of medical officer to a public school, and recommended that the memorandum be adopted and included in the report of the Council.

Dr. Lyndon took exception to certain statements in the memorandum, and Dr. Brackenbury said that as this was a document which would go forward to the public as a statement of the Association's ideas on this matter, he agreed with Dr. Lyndon that some of its phrases might be more guarded. Mr. Harman and the Chairman pointed out other phrases in the report which, if the report was to be a pronouncement of the Association, certainly needed some recasting. Dr. Bone said that as to the accuracy of the statements in the memorandum, these were the statements of the school medical officers themselves, who might be expected to know something about the subject. But he agreed that it would be better to consider the memorandum further and recast it.

A further memorandum outlined what it was proposed should be adopted as the policy of the Association with regard to the remuneration and duties of whole-time medical officers of public schools. The Council discussed this memorandum paragraph by paragraph, and members pointed out certain respects in which the document called for revision. A list of duties was set out, and the memorandum laid it down that the duties of medical officers should not include bacteriological examinations, administration of general anaesthetics (except in emergency) or of anaesthetics for dental work, *x*-ray examinations, refractions, major operations, and attendance on masters outside term time, on families and servants of masters, and on school servants. Dr. Brackenbury did not think that refractions should be one of the things excluded from the duties, and the Chairman hoped that "bacteriological examinations" would not be held to exclude the simpler examinations which a school medical officer certainly ought to do. A further clause, "That satisfactory arrangements should be made in school curriculums whereby medical officers shall have full opportunities of giving instruction to the scholars on questions of health and hygiene," was also criticized as not entirely satisfactory. It was agreed to recast this provision so as to make it read that instruction on health and hygiene should be provided in the curriculum, that the medical officer should be consulted therein, and that the method of instruction to be given to individual boys should be left open. Dr. Dain called attention to the omission from the list of duties of one of the most obvious—namely, the periodical examination of the boys and the keeping of a record.

This memorandum also was taken back for revision in the light of the discussion in the Council.

On a recommendation that all public schools with 400 or more boarders should be provided with a whole-time medical officer, Dr. Dain urged the Council to hesitate before laying it down that this was necessarily a whole-time job. He was afraid there was a tendency for such offices to be filled either by recently qualified men who had had no experience of general practice, or by men who had retired from general practice and desired a quiet post. Mr. McAdam Eccles supported what Dr. Dain had said. At Winchester, a school of 480, the question of appointing a whole-time medical officer was seriously considered two or three years ago, but after paying regard to the experience of other schools the proposal was turned down, and for the reasons practically that Dr. Dain had mentioned. Dr. Buchan thought there was a function for the whole-time school doctor, but that, on account of lack of general experience, his function should not include the treatment of the sick. Mr. Bishop Harman pointed out that there was a type of mind which took kindly to the well defined work of the school medical officer, with its routine and systematic examinations, while, on the other hand, the active general practitioner was averse to this kind of work. He held, therefore, that there was a real place for the whole-time officer. The Chairman asked whether, if it were agreed that all public schools with 400 or more boarders should have a whole-time officer, the number of such officers would be much increased. Mr. Turner said that he believed there were only about thirty such schools (including boys and girls) with over 400 boarders, and that about twenty of these already had whole-time officers.

Another recommendation dealt with the appointment, duties, and method of remuneration of the part-time school medical officer. Dr. Brackenbury pointed out that there was a distinct difference between part-time and whole-time employment in the respect that the part-time officer should not be expected to do several of the things which were set out among the duties of the whole-time officer, and that it was reasonable to suppose that the part-time officer would require more specialist assistance. The feeling of the Council was against a portion of the recommendation which read: "In general the duties of a part-time medical officer should be identical with those of a whole-time medical officer." Dr. Bone promised that the whole matter should be further considered.

Midwifery and Maternity Services.

Dr. Bone said that his committee had considered the Puerperal Fever and Puerperal Pyrexia Regulations which came into operation on October 1st. The question had now been raised as to what fee, if any, the Association proposed to fix for consultants called in under these regulations. The Medico-Political Committee was of opinion that, in view of the varying circumstances in each locality as regards consulting fees, and the distances which might have to be travelled, it would be difficult to fix a fee to suit all areas, and he brought forward a recommendation that it was inadvisable to fix a uniform fee, but that the fee paid should bear some relation to the usual consultation fees in the area.

Dr. Buchan described the position in Middlesex. In Willesden the fee for consultation, fixed personally between himself as medical officer of health and the consultant, was five guineas, but in certain other districts in the county three guineas had been accepted. He wanted guidance from the Association as to the fee to be charged. Dr. Bone pointed out that the Association had to bear in mind the varying conditions of areas, such as rural districts and poor industrial

districts. Dr. Brackenbury thought that in the London and Middlesex area the body to decide was the Metropolitan Counties Branch. Dr. Fothergill moved to add to the recommendation that the matter should be one for arrangement between the representatives of the medical profession and the authority. It was not desirable for the authority to approach and bargain with the individual doctor. Dr. Hillman seconded this addendum. Dr. Buchan said that this did not get over his difficulty, because the consultants who acted in Middlesex were from Harley Street. The Medical Secretary said that there had been a good many applications to headquarters for advice, and to his "unsophisticated mind" the thing looked simple. Everyone knew what the consultant usually charged when called in to a working-class patient; the local authority could hardly be asked to pay more, and certainly should not be asked to pay less, and a Division secretary consulted on the matter should so advise. The recommendation, with Dr. Fothergill's addendum, was carried.

Among other matters in the report of the Medico-Political Committee was the question of medical practitioners engaged in municipal maternity homes, the basis of remuneration for consultative services in such homes, and the payment by local authorities for ante-natal work. The Council decided to recommend to the Representative Body that the principle of payment on a salaried basis for consultative services to municipal maternity hospitals was not unreasonable, but that the actual salary must be governed by the circumstances of each case, and should bear some relation to the remuneration laid down in a resolution of the Representative Meeting, 1926 (not less than three guineas for a consultation when called in by the practitioner in charge of the case, and not less than ten guineas for a *major operation*). *With regard to the instruction given by* the last Representative Meeting to consider the advisability of pressing for the amendment of the Midwives Act in order to secure that local authorities be made responsible for payment for ante-natal work, the Council agreed that, for certain reasons duly set out, it was not advisable to press for this amendment.

The Council had agreed previously that at a convenient time a conference be called of representatives of the Ministry of Health, the Medical Research Council, the Section of Obstetrics and Gynaecology of the Royal Society of Medicine, and the Society of Medical Officers of Health, with the members of the Association's Committee on the Causation of Puerperal Morbidity and Mortality, to consider the interim report of that committee or certain specific points therein. It now agreed to add to the bodies to be invited to send representatives the Royal Colleges of Physicians and Surgeons, the Central Midwives Board, and the Scottish Board of Health.

The Coroners (Amendment) Bill.

Dr. Bone made a statement on the position of the Coroners (Amendment) Bill (see JOURNAL, December 18th, p. 1200), and the financial amendments put forward by the Association. The Chairman expressed the thanks of the Council to Dr. F. E. Fremantle, M.P., and Sir Richard Luce, M.P., for their action in doing their best to support the interests of the profession. It was intimated from the Home Office (in offering an all-round 50 per cent. increase of medical fees) that if the Association persisted in its amendments the bill would be wrecked; the Medico-Political Committee considered that in the circumstances the Association ought not to accept the onus of wrecking the bill, but their representatives in the House had made it plain to the Standing Committee that the Association was by no means satisfied, and that in particular the fee for a *post-mortem examination* (one and a half guineas) was considered quite inadequate.

The Revision of the "British Pharmacopoeia."

Dr. Brackenbury presented a report of the Pharmacopoeia Committee which was appointed in July to watch any steps that might be taken relating to the revision of the *British Pharmacopoeia*, and to prepare evidence and nominate witnesses if a revision committee was appointed by the Lord President of the Privy Council. The Lord President had now remitted the question of the preparation of the *British Pharmacopoeia* to a committee of the Cabinet, and a subcommittee of that body had invited the Association to bring forward its views orally and in writing. The Association's committee accordingly had laid down certain propositions as to the appointment of the committee of experts in whose hands the work of revision should be placed, and it was also considered that this expert committee should be instructed to include in the *Pharmacopoeia* as far as practicable all those drugs and preparations which experience showed to be in common use by medical practitioners, provided that they had a therapeutic or diagnostic value or were pharmaceutically necessary, and that the interests of the public required with regard to these that a standard method of preparation or of strength or purity should be recognized. It was also desired that the committee of experts "should have regard to economy in the inclusion or otherwise of the preparations in the *Pharmacopoeia*, and that regard should be had in this connexion to any drug tariff issued under the National Health Insurance Acts."

Dr. Hawthorne, a member of the committee, dissented from the views of his colleagues. He considered that the direction given to the witnesses who were to appear on the Association's behalf was most unfortunate, and not likely to redound to the credit of the Association. He objected to the constitution of the proposed committee of experts which was concerned with the selection of substances to go into the *Pharmacopoeia* and the technical presentation of such substances. The first of these matters was one which ought to be dealt with only by medical practitioners, and yet among the members proposed were representatives of the Chemical, Physical, and Pharmaceutical Societies. On the other hand, the Pharmacopoeia Committee of the General Medical Council had the necessary qualifications. He also objected to the method of deciding what should be included in the *Pharmacopoeia*. The question would be raised as to what was the therapeutic test which would reduce the number of recognized substances. He was told—*he did not accept the figures—that the substances used* by doctors as medicines numbered 8,000, and if a therapeutic test were applied they would be reduced to 800! That would be tantamount to saying that of ten substances more or less customarily employed by the medical profession nine were useless. He moved:

> That the witnesses who are to appear on behalf of the Association before the Committee on the Revision of the *Pharmacopoeia* be instructed to urge (1) that the selection of the medicinal substances to be included in the *Pharmacopoeia* should be made by the Pharmacopoeia Committee of the General Medical Council, the necessary technical details of the volume being committed to the direction of trained experts; and (2) that the *Pharmacopoeia* ought to include those substances which are being more or less generally prescribed under an official definition of standard in the public interest.

Dr. Clark Trotter seconded the amendment.

Dr. Hawthorne's amendment was lost, and the report was approved.

Hospitals and their Staffs.

Mr. McAdam Eccles, in bringing forward the report of the Hospitals Committee in the absence of its chairman, Mr. Souttar, reported that, in accordance with the resolution of the Council at the last meeting, Sir Richard Luce and the Medical Secretary had visited Paris to confer with the parties interested in the situation which had arisen at the British Hertford Hospital, where the dismissal of the resident medical officer had been followed by the resignation of the medical staff. He thought that the warm thanks of the Council were due to the two emissaries for the most excellent diplomatic work they had done. As a result of their report, he moved that, subject to the approval of the British Ambassador in Paris, the Government be asked to send to Paris some competent and reliable person to consider the whole of the evidence given before the committee of inquiry, the report of that committee, and such other evidence as he might think fit, and to decide whether the Hertford Hospital Committee had done an injustice to the late officer. The important point was that both the committee of management of the hospital and the late medical staff had agreed to accept the decision of such a person. The deputation had done more than was implied in the recommendation, for they had, harmoniously with the hospital authorities, looked into the constitution of the hospital with a view to preventing such a situation arising again. The recommendation was agreed to, and the Council, on the motion of Dr. Lyndon, expressed its thanks to Sir Richard Luce and the Medical Secretary.

A dispute arising in connexion with the Middlesbrough Maternity Hospital was also considered. In this case the Cleveland Division objected to the appointment by the town

council of a consultant to the hospital. The Division held that the choice of consultant should be a matter of agreement between the patient and the medical attendant. The Divisional secretary pointed out that the consultant who had been appointed was a general practitioner doing surgery, and that there were roughly a dozen men in the town doing the same work. The post had never been advertised or thrown open to competition. A long correspondence with the Ministry of Health was read, and it was stated that the Deputy Medical Secretary had discussed the matter with Sir George Newman, who expressed himself in absolute agreement with the principle of free choice of doctor if the patient was going to pay the doctor who was called in, and that patients not in a position to pay should be treated by the appointed consultant. Sir George Newman was satisfied that the consultant who had been appointed was one of the best qualified among those available. With regard to a suggestion that a roster of doctors be formed for summons on emergency, Sir George Newman said that he was not prepared to arrange such a roster until he was satisfied that the members proposed were capable of doing the work. It was decided that the Hospitals Committee should further consider this matter after a report from the North of England Branch Council.

The Association's Premises.

Sir Robert Bolam, as chairman of the Building Committee, made a long statement, part of which was confidential, on the question of the Association's premises, and in particular on the proposed lay-out and use of the land in front of the present building, now occupied by the houses in Tavistock Square and Woburn Place, which have come, or will shortly come, into the Association's possession under the terms of the agreement with the Duke of Bedford's Trustees. He said that the new house of the Association, although apparently offering abundant space, had been found inadequate as to accommodation in some respects, though a certain amount of structural alteration and readjustment within the building might go far to meet the case. At the same time, those in charge had to look ahead for a considerable period and to lay down a policy which would not leave their successors in the position in which they themselves were left in the case of the Strand building. That building provided at first ample accommodation, but presently it came to be encroached upon by office needs, which left almost no room for members' use. The question of standing charges in relation to the premises was also a serious one. In the present headquarters the standing charges—including capitalization of the amount spent on the building, the ground rent of the building and of the land in front, and the annual rates on the existing building—greatly exceeded those of the Strand premises, and the additional cost of completion of the building, with the additional rates, would mean a further large increase. The administration costs of the new building were also higher than in the Strand—a different kind of service and convenience was, quite properly, available for members. Altogether, a heavy burden had to be faced, and, like any private individual, the Association had to determine what proportion of its income could justifiably be set aside for rental and administration. Would members feel satisfied eventually with a great development at headquarters, involving large standing expenditure, or would they call increasingly for what he might describe as devolution expenditure? The tendency in the Association was in this latter direction. There were two courses open to the Council. One was to decide that the greater part of the additional space as it became available should be absorbed for purely headquarters purposes, which would mean heavy standing charges. On the other hand, the Council might decide not to absorb space which might be advantageously let to other kindred societies or for business purposes, and thus secure a large return in rents. Sir Robert Bolam then had plans of the property distributed, and indicated certain possibilities of future development with regard to the premises fronting the main thoroughfare.

Mr. Eccles agreed that to increase the subscription was out of the question, but with its increasing membership the Association could look for an enlargement of its subscription revenue. Dr. Douglas said that only last year the Association came into possession of a very large building, and it was rather strange to hear that it was inadequate. He wanted to know wherein its deficiencies consisted. Mr. Harman said that there had been complaints with regard to inadequate committee-room accommodation, but with certain structural alterations four excellent committee rooms might be provided. The Library was at present cramped for space, but a good deal of space was wasted in certain passages, and these might be brought into the Library to add to the shelving accommodation and the provision for readers. Some superfluous space at present given up to the garages might be used for book storage. With the possible exception of some extension of the printing department, he thought that all the legitimate demands could be satisfied at the headquarters as they stood at present. He wanted the Council to pass a self-denying ordinance that, for this generation, it would not ask for further space for the Association, and that other property which came into the Association's possession should be used, except perhaps in the case of the printing department, for the purpose of earning rents. He agreed with what had been said about the possibility of devolution. Dr. Mackenzie was doubtful whether the potential membership was much more than about 35,000. Almost all the recruitable older members of the profession had been recruited, and entrants into the profession were now diminishing. Any demand for an increased subscription to be spent on lavish headquarters buildings would be resisted. With regard to accommodation for members at the house, he did not think there was any inadequacy. A comfortable Common Room was provided, together with means of getting refreshments. He believed the Association would have to face increased demands from Branches and Divisions, and especially from oversea, which would throw an increased strain on the present subscription.

A number of questions were asked and answered by the Chairman, who gave a rough estimate of the total cost of the scheme he had laid before the Council. The Council agreed unanimously that the scheme which the Chairman had brought forward should be further explored, and that before the next meeting of the Council such documents as the Building Committee could circulate, with due regard to the privacy which must attend any negotiations, should be laid before the members.

Expenses of Committee Members.

The question of the payment of travelling expenses for members of committees was discussed, but no alteration was recommended by the Finance Committee in the existing by-law whereby railway fares only are paid. It was agreed that there were hard cases when members had to attend committee meetings on consecutive days and the distance was too great for them to return home at night. Dr. Douglas pointed out that a member living away from London might be called upon to attend committee meetings twenty times a year—not an unusual number—and even though his railway fare was paid, he was considerably out of pocket. Dr. Fothergill moved an instruction to the Organization Committee to consider the question of a subsistence allowance, but it was pointed out that this must raise the question of expenses of representatives attending the Representative Meetings, as well as members of Council and committees, and would involve, if granted, a very large expenditure. The motion was lost.

The Association's Ophthalmic List.

Dr. Wallace Henry, chairman of the Ophthalmic Committee, brought forward a recommendation that before the name of any practitioner was added to the Association's ophthalmic list the Local Medical Committee of the area concerned should be given the opportunity of furnishing information as to the eligibility of the applicant if it had previously expressed a desire to be consulted. He remarked that up to now the information received from Local Medical Committees had been of very little value. The recommendation was agreed to.

It was also agreed to ask the Scottish Committee to nominate a member for the Ophthalmic Committee. Dr. Miller desired that a special subcommittee should be formed for Scotland, and reminded the Council that in Scotland they had to deal with the Scottish Board of Health, not with the English Ministry. The Chairman said that it was the wiser course to deal with Scottish applications through the Ophthalmic Committee, so that the national policy might be homogeneous, giving that committee advice on purely Scottish points, through a member to be nominated by the Scottish Committee.

The Medical Association of South Africa (British Medical Association).

On the recommendation of the Organization Committee, the Council approved a draft memorandum and articles of associa-

tion of the Medical Association of South Africa—*Die Mediese Vereniging van Suid-Afrika*—(British Medical Association), subject to certain adjustments and to the approval of the existing Branches in the Union of South Africa and the Mandated Territory of South-West Africa. The Council also agreed, subject to the acceptance by the Federal Council of the safeguards which had been incorporated by the Organization Committee in the memorandum and articles, to assist in meeting the expenses of the Federal Council in organizing the profession by a grant of £1,000 a year for two years. Dr. Morton Mackenzie reminded the Council that it had agreed in 1924 to grant a sum of £1,000 a year for three years to meet half the cost of the appointment of an organizing secretary for South Africa. There were various difficulties in the way of such an appointment at that time, and the visit of the Medical Secretary to South Africa was regarded as equivalent to the first year's contribution. The proposal which now came from South Africa was rather different. The Federal Council had resolved to purchase the *South African Medical Record*, to amalgamate therewith the *Medical Journal of South Africa*, an organ published in the Transvaal by a company which was in effect the local Branch of the Association, and thus to establish an official journal. The engagement of the present editor of the *Record*, Dr. Darley Hartley, was to be continued for one year as joint-editor, after which he would be pensioned, and the other joint-editor was to be Dr. C. L. Leipoldt, who would also act as organizing secretary. Dr. Mackenzie urged the Council to make the grant, although admittedly the new proposal was not on all fours with the previous one. Mr. Harman said that the Finance Committee took no exception. Dr. Lyndon and Dr. Bone also supported the new proposal; and the Medical Secretary said he hoped the Council would not turn the proposal down, because to do so would give a handle to the few people in South Africa who declared that there was some "catch" in the federation arrangements. He believed that this arrangement would enable Dr. Orenstein, now president of the Federal Council, to put the coping-stone on the work already done. For South Africa to have a journal of its own, as Australia had, would go far towards consolidating the movement. The proposal to make the grant was carried unanimously.

Medical Profession in India.

Sir Jenner Verrall, in presenting the report of the Dominions Committee, said that the committee had set up a subcommittee to make a preliminary investigation on the relation of the Association to the profession in India. It would begin by collecting information from and ascertaining the opinions of the Indian Branches and of individual Indian practitioners. He also mentioned that a bill to regulate medical education in India had been submitted to the Burma Branch of the Association by certain departments of the Government of Burma. On the ground that the proposed "Council of Medical Education" would establish a system whereby the names of duly qualified medical practitioners and practitioners of indigenous systems of medicine were included on the same register, the Association would feel bound to protest against this bill, but he (Sir Jenner) believed that the bill was already dead.

The Charities Trust Fund.

Dr. Walker brought forward the report of the Charities Committee, which, he said, was still doing spade work, and hoped to show larger results later on. The Financial Secretary, in reply to a question, said that more money had been collected this year than before, but there were no means of knowing as yet what proportion of money which now came through the Association had previously been subscribed direct to the individual charities. Dr. Bone suggested that Panel Committees might be asked to send their collected subscriptions through the Association, while at the same time retaining their voting power in their localities. Dr. Greenfield described some effective work which had been done in his own county. Members of the profession who had not responded after appeals from the Panel Committee and the Division would be approached personally, and he hoped eventually to have 90 per cent. of the profession contributing. The Chairman said that if he were a charities secretary in a Division he would make a card index of members, and would find out what each member had subscribed in the past for medical charities, and get him to send his money through the Association. A proportion of such money would be left to the discretion of the Charities Committee for its allocation, and another proportion would be earmarked for a particular charity, the ear-marked money being in some cases accompanied by a request for the corresponding voting power. Dr. Lyndon mentioned the appeal of Epsom College for a new sanatorium and isolation block (JOURNAL, December 18th, p. 1195), and suggested that the money now proposed to be allocated to Epsom College be sent to that special fund. This was accepted by Dr. Walker and agreed to. Dr. Walker also advocated the establishment of a branch of the Ladies' Guild of the Royal Medical Benevolent Fund in as many Divisional areas as possible in order to enlist the support of doctors' wives. He expressed appreciation, also voiced by the Chairman, of the very considerable contributions which the Medical Insurance Agency had made to the charities.

Other Business.

Many other reports of committees were approved during the two-day session. Among these were the report of the Insurance Acts Committee, which was a record of action taken; the Arrangements Committee, chiefly concerned with the appointment of officers of Sections for the Annual Meeting in Edinburgh next July; the Science Committee, which dealt with the facilities of the Library and with certain matters connected with the competitions for Association awards and prizes; the Committee on Tests for Drunkenness, which was stated to be now considering its draft report; the Office and Journal Committees, which were of a routine nature; and the conference between representatives of the Association and the Society of Medical Officers of Health, at which, among other things, it was agreed by the representatives, subject to the approval of the respective councils, that no members of the society should be advised *collectively* to apply for increases of salary, using the scale as the chief argument, until the Public Health Committee of the Association had been consulted. The Council reappointed its Lunacy Law and Administration Committee, to consider the report of the Royal Commission, and also, in accordance with a resolution of the Representative Meeting, the situation arising from the findings of the jury in the case of Harnett v. Fisher, with a view to protecting the interests of the profession.

Association Notices.

BRANCH AND DIVISION MEETINGS TO BE HELD.

BIRMINGHAM BRANCH: NUNEATON AND TAMWORTH DIVISION.—A meeting of the Nuneaton and Tamworth Division will be held at the Nuneaton General Hospital on Wednesday, January 5th, when Mr. J. B. Leather, F.R.C.S., will discuss abdominal injuries.

BIRMINGHAM BRANCH: WEST BROMWICH DIVISION.—The annual meeting of the West Bromwich Division will be held at the District Hospital, West Bromwich, on Tuesday, January 11th, at 3 p.m. Agenda: Résumé by retiring chairman of the work of the Division during 1926; election of officers for 1927; programme for 1927; alteration of Rule 12 (1)—the Executive Committee suggests that the rule be altered to read: "Ordinary meetings of the Division shall be held during the months of January, April, June, and October (three meetings in West Bromwich, one meeting in Smethwick)"; formation of local Hospitals Committee; medical charities; chairman's address.

BORDER COUNTIES BRANCH: DUMFRIES AND GALLOWAY DIVISION.—The next meeting of the Dumfries and Galloway Division will be held in the Royal Infirmary, Dumfries, on Thursday, January 13th, at 3.30 p.m., when, in addition to the routine business, an important report on the hospital accommodation of the area will be considered.

GLASGOW AND WEST OF SCOTLAND BRANCH: LANARKSHIRE DIVISION.—A meeting of the Lanarkshire Division will be held at the Masonic Hall, Hamilton, on Tuesday, January 11th, at 8.30 p.m. Dr. John Glaister will read a paper on "The medical man in the witness-box."

METROPOLITAN COUNTIES BRANCH: CITY DIVISION.—The next meeting of the City Division will be held at the Metropolitan Hospital on Tuesday, January 4th, at 9.30 p.m. Mr. Acton Davis, F.R.C.S., will read a paper on osteomyelitis. It is hoped there will be a large attendance. Coffee will be served. The next clinical meeting of the City Division will be held at the Metropolitan Hospital on Friday afternoon, January 14th, at 4.15, when Dr. Norman Hill will show cases. Tea at 4 o'clock.

METROPOLITAN COUNTIES BRANCH: FINCHLEY DIVISION.—A meeting of the Finchley Division will be held at the Finchley Memorial Hospital on Tuesday, January 11th, at 8.45 p.m., when Dr. George Riddoch will give an address on "The early diagnosis of disseminated sclerosis."

METROPOLITAN COUNTIES BRANCH: HAMPSTEAD DIVISION.—A meeting of the Hampstead Division will be held on Thursday, January 13th, at 8.30 p.m. Dr. W. J. Adie (physician to the National Hospital, Queen Square, W.C.) will speak on "Some fits and seizures."

METROPOLITAN COUNTIES BRANCH: KENSINGTON DIVISION.—A ball, arranged by the Kensington Division in aid of the Royal Medical Benevolent Fund, will be held at the Kensington Town Hall on Tuesday, January 11th, from 9 to 2 o'clock. The ball is under the patronage of H.R.H. the Princess Louise Duchess of Argyll. The Clifford Essex Band will play. The price of tickets is one guinea each or six for five guineas; they may be obtained from the Honorary Secretary, 20, Upper Phillimore Place, Kensington, or from any member of the Executive Committee.

METROPOLITAN COUNTIES BRANCH: LEWISHAM DIVISION.—A meeting of the Lewisham Division will be held at the Town Hall, Catford, S.E.6, on Tuesday, January 18th, at 8.45 p.m. Mr. C. A. Joll, F.R.C.S., will give an address on "The diagnosis and treatment of diseases of the gall bladder and bile ducts."

METROPOLITAN COUNTIES BRANCH: NORTH MIDDLESEX DIVISION.—At the meeting of the North Middlesex Division to be held on Wednesday, January 26th, a discussion on insulin will be opened by Dr. G. Grant Macdonald.

METROPOLITAN COUNTIES BRANCH: ST. PANCRAS DIVISION.—At the meeting of the St. Pancras Division to be held at the British Medical Association House, Tavistock Square, W.C., on Tuesday, January 11th, at 9 p.m., Dr. H. C. Cameron will give an address on "Nursery psychotherapeutics."

NORTH OF ENGLAND BRANCH.—A scientific meeting of the North of England Branch will be held at the Royal Victoria Infirmary, Newcastle-on-Tyne, on Thursday, January 20th—2.15 p.m., Sir Thomas Oliver: Heart disease and pregnancy; 2.45 p.m., Mr. J. B. McDougall: Occupational therapy as an adjunct to the treatment of pulmonary tuberculosis; 3.15 p.m., Mr. Glen Davison: The N.C.P. method of dieting the sick infant; 3.45 p.m., tea; 4 p.m., Mr. Grey Turner: Difficulty in swallowing; 4.30 p.m., Dr. Whately Davidson: X-ray diagnosis of disorders of the alimentary tract.

NORTH OF ENGLAND BRANCH: BISHOP AUCKLAND DIVISION.—At the meeting of the Bishop Auckland Division arranged for Friday, January 28th, Dr. A. T. Paterson (Durham) will lecture on "Some common ailments of the eye."

SOUTHERN BRANCH: PORTSMOUTH DIVISION.—The Executive Committee of the Portsmouth Division has arranged a *souper dansant* to be held at the Esplanade Assembly Rooms, Southsea, on Tuesday, January 11th. Dancing will be from 9 p.m. to 2 a.m., and supper will be served at any time between these hours. Tickets, 10s. each (including supper), can be obtained from members or from the honorary secretary, Dr. H. H. Warren, Devonia, Goldsmith Avenue, Southsea. Tickets are strictly limited to 300. Any profit made from the *souper dansant* will be devoted to medical charities. The next monthly meeting of the Division will be held at the Queen's Hotel, Southsea, on Thursday, January 13th, at 9.30 p.m. Supper will, as usual, be served at 9 o'clock precisely. At the conclusion of the business Dr. Thomas Beaton, O.B.E., Portsmouth Mental Hospital, will give an address on "The recognition and management of the mental patient in general practice." Members who intend to be present at supper are particularly requested to notify the honorary secretary, Dr. H. H. Warren, on or before Monday, January 10th.

SURREY BRANCH: CROYDON DIVISION.—A meeting of the Croydon Division, in conjunction with the Dental Society, will be held at the Croydon General Hospital on Tuesday, January 25th, at 8.30 p.m., when Mr. Lewin Payne will read a paper on "Dental conditions and disease."

SURREY BRANCH: GUILDFORD DIVISION.—An ordinary and clinical meeting of the Guildford Division will be held at the Royal Surrey County Hospital, Guildford, on Thursday, January 6th, at 4 p.m. (tea served at 3.45).

SURREY BRANCH: REIGATE DIVISION.—A meeting of the Reigate Division will be held at the East Surrey Hospital, Reigate, on Tuesday, January 11th, at 8.45 p.m. Dr. Stoddart will read a paper on "The certification of mental patients."

SUSSEX BRANCH: BRIGHTON DIVISION.—A meeting of the Brighton Division will be held at the Royal Sussex County Hospital, Brighton, on Wednesday, January 19th, at 3.45 p.m.

YORKSHIRE BRANCH: DEWSBURY DIVISION.—A meeting of the Dewsbury Division will be held at the Man and Saddle Restaurant, Dewsbury, on Tuesday, January 11th. Coffee served at 8.15 p.m. Dr. W. Macadam (Leeds) will read a paper on "Abdominal pain—its various types and their differentiation." Members from neighbouring Divisions will be welcome.

YORKSHIRE BRANCH: WAKEFIELD, PONTEFRACT, AND CASTLEFORD DIVISION.—A meeting of the Wakefield, Pontefract, and Castleford Division will be held at the Bull Restaurant, Westgate, Wakefield, on Thursday, January 13th, when Dr. T. W. Griffith, consulting physician, Leeds General Infirmary, will give a lecture on "The prevention of heart disease and the causes and treatment of irregular heart action." Supper at 7.45 p.m. (2s. 6d.) will precede the lecture.

Meetings of Branches and Divisions.

BIRMINGHAM BRANCH.

THE second ordinary meeting of the Birmingham Branch took place on December 16th, 1926, with the President, Dr. H. G. DAIN, in the chair. A very instructive paper was read by Mr. C. A. RAISON, F.R.C.S., on "The acuto abdomen in the child." The main plea of the paper was for early diagnosis of the abdominal emergencies in childhood, and Mr. Raison pointed out that with the present improvements in operative technique the chief prospect of reducing the mortality lay in the diagnostic acumen of the general practitioner who first saw the case. He dealt at some length with the clinical features of intussusception, acute appendicitis, pneumococcal peritonitis, and acute obstruction; and illustrated his remarks with charts bringing out the main points in the differential diagnosis, and his own operative mortality during the last four years.

A general discussion followed, and the meeting closed with a vote of thanks to Mr. Raison.

BIRMINGHAM BRANCH: NUNEATON AND TAMWORTH DIVISION.

A MEETING of the Nuneaton and Tamworth Division, postponed from November 25th, was held at the Tamworth General Hospital on December 16th, 1926.

Dr. L. G. PARSONS read a paper entitled "Some problems of nephritis in children." He described the physiology of the secretion of urine in the light of the most recent research, and then discussed the pathology of various forms of nephritis in children. He also discussed the use of renal efficiency tests and the principles underlying their employment. The lecture was illustrated by diagrams.

A discussion followed in which several members took part. Dr. Parsons subsequently replied to various questions raised during the discussion, and a vote of thanks to him for his most interesting lecture was carried unanimously.

DORSET AND WEST HANTS BRANCH: WEST DORSET DIVISION.

A MEETING of the West Dorset Division was held at the Yeovil Hospital on December 9th, 1926, when nineteen members were present.

Dr. H. A. UNWIN showed three cases: (1) A young woman suffering from Addison's disease. There was an unusual amount of pigmentation. Carbohydrate metabolism was normal, and so was the basal metabolic rate. The blood count was normal. It was proposed to make a graft of some portion of a suprerenal gland, but the patient was unwilling to submit. (2) An elderly woman suffering from myxoedema. This case had now been treated, but photographs showed the condition prior to treatment. It was noteworthy that a photograph as a young girl showed evidences of exophthalmic goitre. The patient had been treated in the United States of America for many years as a case of renal disease. (3) Case of scorbutic infantilism. Photographs were again shown of different stages of this patient's progress. Some excellent and remarkable *x*-ray photographs had been taken when the case was at its worst, and these had been published in a paper and were on view. The patient, a boy, had persistently refused to eat any vegetables or fruit, and extracts of green vegetables, etc., had had to be made and given as medicine. At one time the boy was confined to bed and both arms and legs were contracted. There were spontaneous fractures of both femurs. The boy was now able to walk and in fair health.

Dr. A. T. TODD, O.B.E., assistant physician to the Bristol Royal Infirmary, read a paper on chronic arthritis. This paper dealt first with etiology and then with treatment, and contained an interesting and stimulating account of some new work on the disease. At the close he was warmly thanked, and the hope was expressed that he would soon publish the paper, which would repay careful study. Members were afterwards entertained at tea by the staff of the hospital.

EDINBURGH BRANCH: LOTHIANS DIVISION.

A MEETING of the Lothians Division was held in Ferguson and Forrester's Restaurant, Princes Street, Edinburgh, on December 9th, 1926. The meeting was an innovation in the history of the Division. Dr. R. W. CRAIG presided, and there was a fair attendance of members from over a wide area. After supper Dr. WILLIAM FORDYCE, F.R.C.P.E., gave a short address on "Pitfalls in obstetric and gynaecological practice," which was much appreciated. Thereafter Drs. DREVER (Scottish Medical Secretary), EASTERBROOK, TORRANCE, MCLEAN, FORDYCE, and others contributed to a varied programme, and the hope was expressed that similar gatherings would be held in the future.

ESSEX BRANCH: MID-ESSEX DIVISION.

A MEETING of the Mid-Essex Division was held at the Chelmsford Hospital on December 17th, 1926, when Dr. VERCOE was in the chair.

The recommendation of the committee regarding salaries of whole-time public health officers was received and adopted unanimously. The recommendation that the Branch be advised to take similar action was carried unanimously. The secretary was instructed to inquire what action the Executive of the British Medical Association was taking to secure a standard rate of remuneration for part-time public health medical officers. The question of appointing a consultant to deal with cases of puerperal pyrexia and fever was discussed at length by Dr. Bullough

(county medical officer) and others, and the following recommendations were carried:

(a) That where necessary institutional treatment should be provided for cases of puerperal pyrexia and fever notified by practitioners.

(b) That provision should be made whereby a doctor in charge of a case of puerperal pyrexia or fever (duly notified) could call in a second opinion.

(c) That the fee for such a consultation paid to the consultant in the case of the consultant being a general practitioner be not less than £2 2s.

(d) That the services of a recognized obstetric specialist be provided at the discretion of the notification of births authority.

(e) That ambulance transport for cases of puerperal pyrexia or fever be provided at the expense of the authority concerned.

After tea a very interesting demonstration of x-ray photographs was given in the x-ray department of the Chelmsford Hospital by Dr. L. M. BILLINGHAM, radiologist to the hospital.

JAMAICA BRANCH.

A MEETING of the Jamaica Branch was held on November 18th, 1926, in the Public General Hospital, Kingston.

Dr. B. M. WILSON, Principal Medical Officer, Jamaica, opened a discussion on yaws and syphilis, and propounded the thesis that an untreated attack of yaws protected against an attack of syphilis, but that an attack of syphilis did not protect against an attack of yaws. Drs. ALLEN, STIMPSON, SMITH, VINE, JOHNSON, and Major DAWSON took part in the discussion. On the motion of Dr. C. A. H. THOMSON, seconded by Dr. ALLEN, a vote of thanks was accorded to Dr. WILSON.

LANCASHIRE AND CHESHIRE BRANCH: ST. HELENS DIVISION.

A MEETING of the St. Helens Division was held at the Fleece Hotel on December 10th, 1926.

It was unanimously decided to adopt the following resolution in connexion with the scale of minimum commencing salaries for medical officers of health, etc., under Ethical Rules:

> That in the opinion of the St. Helens Division no medical practitioner should apply for any public health appointment within the area of the Division the salary of which does not conform to the scale of minimum commencing salaries for whole-time chief medical officers of health and medical officers of other grades and/or for combined posts of those medical officers who are employed by more than one authority, as approved and adopted as the policy of the Association at the Annual Representative Meeting at Bath, 1925, or continue to hold any such appointment made after December 10th, 1926, at a lower rate of remuneration than that applicable thereto as contained in and laid down by the said scale.

The proposal had previously been adopted by the Branch. The questions of certification and of maternity fees were discussed, but no resolutions were adopted.

METROPOLITAN COUNTIES BRANCH: CITY DIVISION.

THE annual dinner of the City Division was held in the Balmoral Room, Trocadero Restaurant, on December 2nd, 1926, when eighty-two members and their guests were present, under the chairmanship of Dr. HAROLD LATHAM. A most excellent dinner was enjoyed by all, and the speeches were short and entertaining. Among those who spoke were the CHAIRMAN, Dr. G. C. ANDERSON (Deputy Medical Secretary), the Rev. A. MACLEAN (rector of South Hackney), the Rev. MOSTYN JONES, D.D., Dr. PHILIP HAMILL, Dr. G. CLARK TROTTER, and Dr. CUTHBERT DIXON. Musical entertainment which delighted everyone was provided during the evening by Mrs. Westerman and Mr. Ernest Hastings, the thanks of the Division being especially due to Mrs. Westerman for her most generous and ready help.

METROPOLITAN COUNTIES BRANCH: TOWER HAMLETS DIVISION.

A CLINICAL meeting of the Tower Hamlets Division was held on December 8th, 1926, at the Mile End Hospital, when about forty members were present.

Dr. GILL showed a series of cases of fibrosis of the lung in young children, illustrated by radiographs, and dwelt on the differences between tuberculous and non-tuberculous types. Dr. WHIGHAM showed a series of gastric cases and compared the results of medical and surgical treatment. Dr. COYLE demonstrated a number of interesting conditions, including cases of congenital club-hand, sarcoma of the mastoid, encephalitis lethargica commencing with a generalized rash, and an unusual case of disseminated sclerosis. Dr. SCURLOCK and Dr. FANNING showed several cases for diagnosis.

A discussion ensued in which members participated, and the proceedings terminated with a vote of thanks to Dr. J. J. Wilson, the medical superintendent.

NORTHERN COUNTIES OF SCOTLAND BRANCH: BANFF, MORAY, AND NAIRN DIVISION.

A LARGELY attended meeting of the Banff, Moray, and Nairn Division was held in the Gordon Arms Hotel, Elgin, on November 26th, 1926, on the occasion of the visit of Professor D. P. D. Wilkie, of the Chair of Surgery in the University of Edinburgh, to deliver a British Medical Association Lecture. The Scottish Medical Secretary was present, and several members of other Divisions of the Branch. Dr. R. DOUGLAS (medical officer of health for the counties of Moray and Nairn), chairman of the Division, presided, and in a few words introduced Professor WILKIE, who spoke for over an hour to a most appreciative audience on "Pain on the right side of the abdomen," pointing out the varieties, causes, and differential diagnosis of the various types of acute and chronic pain in that particular area. The lecture was greatly enhanced by the exhibition of about fifty lantern slides, many of actual operation specimens, and others of radiograms illustrating the most modern methods of diagnosing biliary and renal conditions. At the close of the lecture the President of the Branch, Dr. E. T. MACKENZIE (Tain), said he had come over eighty miles to hear the lecture, and had been rewarded by a rare surgical treat, and he envied the students of to-day in having such a lecturer and such wonderful teaching at their disposal. Dr. J. STEPHEN, D.S.O. (Banff), in proposing a very hearty vote of thanks to Professor Wilkie for his lecture, said it would long be remembered in the area. The motion was carried with acclamation, and was briefly acknowledged by the lecturer.

At a later hour in the evening about thirty members of the Division sat down to dinner, under the chairmanship of Dr. DOUGLAS, the guests being the lecturer of the afternoon, the Scottish Medical Secretary, the Lord Provost of Elgin, and the Sheriff Clerk of the county. In replying to the toast of his health, which had been proposed by Dr. JOHN TAYLOR, senior surgeon to Gray's Hospital, Elgin, Professor WILKIE delivered a racy reply, with reminiscences of his recent visit to Canada and the United States, and contrasted very clearly hospital methods on each side of the Atlantic. Other toasts followed, and a most enjoyable evening terminated with the singing of "Auld lang syne."

PERTH BRANCH.

AT a meeting of the Perth Branch Council held in October last it was resolved to arrange for the presentation of an illuminated address to Dr. Leigh Hunt in commemoration of his having been *in practice for more than half a century.* Dr. Hunt became a member of the British Medical Association in 1880, served as a member of the Perth Branch Council, 1894-96 and 1904-05, was vice-president of the Branch in 1894, and president thereof in 1895. It was arranged that the presentation should take place at the annual dinner of the Branch, provided that Dr. Hunt's health permitted him to be present as a guest of honour, otherwise it was agreed to send a deputation to make the presentation.

At the dinner, held on November 17th, 1926, Mr. STIRLING, who presided, referred to the sterling qualities of Dr. Hunt and to his popularity with his colleagues and the public in general. Dr. Hunt had served for twenty-five years on the staff of the Perth Royal Infirmary, was at present medical officer to the parish council, and up to a few weeks ago was attending his private and panel patients as usual. Other speakers referred in eulogistic terms to Dr. Hunt's services to the community and the profession. Dr. JOHN STEVENS (Edinburgh) spoke of the conscientious manner in which Dr. Hunt had conducted his work throughout his long career. Dr. DREVER, the Scottish Medical Secretary, gave an interesting address on the activities of the Association.

As Dr. Hunt was unable to attend the dinner a deputation, consisting of the President of the Branch (Dr. Menzies), Dr. Hume, and Dr. Parker Stewart, waited upon him on November 19th to present him, on behalf of his colleagues and friends, with an illuminated address and a wallet containing Treasury notes. Dr. Hunt was deeply touched by the gift, and desired the deputation to convey his thanks to the Branch and his colleagues for their kindness.

At a further meeting held on December 10th it was resolved to form a committee to arrange for lectures on scientific subjects, the first to take place on January 27th.

SOUTHERN BRANCH: PORTSMOUTH DIVISION.

THE usual monthly meeting of the Portsmouth Division was held at the Queen's Hostel, Southsea, on December 9th, 1926, and was preceded by supper at 9 p.m., Dr. A. MEARNS FRASER presiding.

After the business had been concluded an address was given by Dr. HERBERT FRENCH, physician to Guy's Hospital. Among the principal subjects he dealt with were: (1) A plea for the wider use of venesection by the needle and bottle method in chronic conditions such as plethora, arterio-sclerosis, and high blood pressure. (2) Illnesses simulating microbic toxaemias, but sometimes caused by gaseous poisons such as coal-gas products and other vapours. (3) The gist of insulin treatment reduced to its simplest practical terms.

Dr. French's address was greatly appreciated and was followed by a good discussion. The meeting was most successful, and on the proposal of Dr. ASTON KEY, seconded by Dr. MONTAGUE WAY, a very hearty vote of thanks was accorded to the lecturer. Ninety members attended the meeting, of whom forty-eight sat down to supper.

SUFFOLK BRANCH: WEST SUFFOLK DIVISION.

A MEETING of the West Suffolk Division was held at the West Suffolk General Hospital, Bury St. Edmunds, on December 14th, 1926, when Dr. J. R. DOBBIN was in the chair.

Dr. GRACE GRIFFITH opened a discussion with some notes on proprietary remedies. She dealt very fully with the difficulties which confronted the general practitioner in attempting to decide whether any of the remedies abundantly advertised by manufacturing chemists were useful or not. She briefly discussed the various groups of proprietary articles, such as colloidal preparations, patent foods, aperients, cod-liver oil preparations, endocrines, vaccines, and serums, and alluded to some of the substances which she had found useful. She pointed out that one of the chief difficulties encountered was lack of knowledge as to the reliability of the advertising firm, and as to whether the chemical constitution of a substance was really as stated in the advertisements.

Drs. HINNELL, BARWELL, STIFF, ALEXANDER, and BATT took part in the subsequent discussion. It was generally agreed that it was

impossible to decide which of the preparations advertised were really useful, and it was suggested that it would be better if the Medical Research Council could test preparations before they were put on the market. On the motion of the CHAIRMAN a vote of thanks was accorded to Dr. Griffith for the trouble she had taken in preparing her notes.

Dr. BATT showed a case of actinomycosis of the appendix region, apparently cured by administration of potassium iodide and stock staphylococcus vaccine.

The sum of £4 5s. was collected on behalf of the Hospital Christmas Fund and handed over to the secretary of the hospital.

YORKSHIRE BRANCH: WAKEFIELD, PONTEFRACT, AND CASTLEFORD DIVISION.

A MEETING of the Wakefield, Pontefract, and Castleford Division was held at the Great Bull Restaurant, Wakefield, on December 15th, 1926, when Dr. GIBSON was in the chair.

In the course of a very interesting and informative address Mr. H. LEE described all the acute diseases of the eye in detail with their treatment. He emphasized the need for free and early incision of lacrymal abscess. In his opinion the best treatment for all forms of conjunctivitis was a single brushing with a 1 per cent. solution of silver nitrate, and subsequent washing with saline solution. He drew attention to the fact that eyes which did not dilate readily with atropine in cases of iritis would always do so if a leech was applied over the temple. He considered that sudden loss of vision in both eyes was practically always a neurosis. Mr. Lee described a premonitory form of glaucoma which was characterized by a sensation of rainbow haloes around lights, together with transient attacks of obscuration of vision, and relieved by eserine; he did not recommend iridectomy at this early stage.

Drs. GIBSON, EARDLEY, BUTLER, THOMAS, GREAVES, RADCLIFFE, and WELLS contributed to the subsequent discussion.

National Insurance.

THE following notice, signed by the secretary of the States Insurance Authority for the island of Guernsey, has lately appeared in the *Guernsey Evening Press*: "Several workers having obtained treatment from bone-setters and other unqualified persons with disastrous results, the States Insurance Authority remind all persons concerned that certificates from legally qualified medical practitioners only are accepted at this office. *Attention* is also drawn to the law which prohibits persons from carrying on the profession of physician or surgeon *without* having been admitted by the Royal Court. In their own interests workers are again asked to obtain medical attention within twenty-four hours of the taking place of an accident."

LONDON PANEL COMMITTEE.

Medical Certification for Sickness Benefit.

AT the meeting of the London Panel Committee on December 21st, 1926, Dr. H. J. CARDALE in the chair, the Panel Service Subcommittee stated that it had had under consideration the memorandum circulated to committees by the Insurance Acts Committee, drawing attention to the increased claims for sickness benefit, and pointing out that practitioners must not be led away by their sympathy for the economic position of the insured person into giving certificates which rightly should relate only to his physical capacity. The subcommittee had decided that a letter in this sense should be sent to all insurance practitioners in the London area. The CHAIRMAN said that this matter arose out of the address by Sir Walter Kinnear at the recent Panel Conference (SUPPLEMENT, October 30th, 1926, p. 193). Sir Walter Kinnear had placed the position before the representatives in a very *convincing* way, and the representatives gave a guarantee that they would do their best to impress on insurance practitioners generally the need for care in certification. The Chairman added that cases were not unknown in which practitioners had been asked by lodges to certify their members *en bloc*, the object being that the lodges might be relieved from the necessity of giving out-of-work pay. There was no special reference to London in Sir Walter Kinnear's remarks.

Dr. V. S. PARTRIDGE thought it a matter for regret that the accusation that there had been any widespread laxity in medical certification should have been accepted without quarrel by the representatives of insurance practitioners. The CHAIRMAN said that the representatives had no help for it; they were confronted by hard figures. Dr. PARTRIDGE said that he did not controvert the figures, but only the inference based upon them. An accusation of general laxity, or what some people might more charitably call misplaced sympathy, on the part of the profession was not one which should have been taken as calmly as it had been. Every insurance practitioner knew that there were many persons on his list who managed to carry on with their work so long as work was available, although, if the practitioner were asked to certify them, he would have no hesitation in pronouncing them unfit. When employment ceased, these people came up for certification, and no practitioner could honestly refuse them. There were a larger number of people of this kind than the Ministry of Health imagined. The speaker could quite conceive an increase in the number of sickness claims by 100 per cent. or more without any imputation of dishonesty.

Dr. G. F. STEBBING thought that the communication from the Insurance Acts Committee might have been worded more carefully and less provocatively.

The CHAIRMAN said that the committee could not take up the position that there was no laxity—that would be to play the part of the ostrich. There was not the slightest doubt that influences had been brought to bear upon practitioners, and that a number had been foolish enough to yield. He did not think that the majority of practitioners were giving improper certificates, but the accusation applied to a considerable minority.

Dr. E. A. GREGG said that Dr. Partridge had taken a line for which, from one standpoint, there was much to be said, but he had failed to realize that Sir Walter Kinnear had given a very generous interpretation to points similar to those which Dr. Partridge had mentioned, and after making the most generous allowance there still remained an excessive number of claims.

Dr. H. B. MORGAN protested against any charge of laxity being brought against the profession. He did not believe that in any area any considerable body of men had been guilty of that which, if proved against them, would render them liable to be dealt with by the General Medical Council. It had been said that in certain districts where the mining dispute had been most critical whole lodges had gone to practitioners asking for their members to be certified. It was due to the profession and the public that full details of such a charge should be given, and the matter laid open for investigation. There might be individual cases in which improper certification seemed probable, though even with regard to these he would like to have the evidence submitted to the closest scrutiny. There would always, of course, be honest disagreement as to whether or not a man was fit for work, but he thought it extremely regrettable that a stigma should have been cast upon the profession.

The CHAIRMAN said that the speech made to the Conference by Sir Walter Kinnear was the fairest he had ever heard from any official of the Ministry. Dr. MORGAN said that it did not read so in the report in the BRITISH MEDICAL JOURNAL. Dr. PALMER said that not only did Sir Walter Kinnear allow for all the possibilities which could explain a legitimate increase in claims, but he seemed anxious to find an excuse for the conduct of which he complained, and it was certainly remarkable that not a single representative present rose to protest. Dr. MORGAN: The Conference was chloroformed by Sir Walter Kinnear. Dr. GREGG said that Sir Walter Kinnear had made a most moderate and restrained speech, and had framed no general accusation.

Dr. PARTRIDGE asked whether the Ministry of Health proposed to take any action against the doctors charged with this conduct. The CHAIRMAN said that in the ordinary way a complaint would go to the Medical Service Subcommittee. Dr. PARTRIDGE argued that recourse should surely be had to the General Medical Council if the facts were as stated.

The letter which it was proposed to send to London insurance practitioners, incorporating a long extract from the speech of Sir Walter Kinnear, was approved by 19 votes to 4.

Correspondence.

Panel Patients and Extra Fees.

SIR,—I hope the letter of Dr. John Wilson (December 11th, 1926, p. 250) will not be allowed to pass without some comment, and I trust also contradiction.

A panel of 700 patients, representing about £280 per annum, he describes as a nice little income, and this after at least five years' hard and continuous study and expense to our parents. At the service of the public for twenty-four hours each day and seven days a week, with all its responsibilities, for the same remuneration as a lady school teacher, and less than most male teachers!

Dr. Wilson goes on to say that usually the private practice is worth at least as much as the panel, and probably a good deal more in the vast majority of cases. I should be glad to know the experiences of some other medical men if this is really the case. In my own practice—and I have been on the panel since its inception—my private work is considerably less than one-fourth of the panel.

I enclose my card.—I am, etc.,

ANOTHER-M.B.

Naval and Military Appointments.

ROYAL NAVAL MEDICAL SERVICE.

Surgeon Commanders G. Nunn, O.B.E., to the *Egmont*, additional, and for Malta Dockyard; H. E. Y. White, M.V.O., O.B.E., to the *Renown*; P. B. Egan to the *Benbow*.

Surgeon Lieutenants E. E. Malone to the *Keppel*; D. Bell to the *Hollyhock*; J. G. Maguire to the *Moth*; H. Gow to the *Scarab*; V. H. Boobbyer to the *Marshal Soult*; W. C. Sloan to the *Marlborough* (appointment to the *Ormonde* cancelled); A. S. Nicol to the *Hood*.

N. A. Dickinson to be Surgeon Lieutenant.

ROYAL ARMY MEDICAL CORPS.

Major W. J. E. Bell, D.S.O., and Captain T. H. Twigg are seconded for service under the Colonial Office.

The following Captains to be Majors: G. F. Carr, M.C. (prov.), B. H. C. Lea-Wilson (prov. and remains seconded).

Captain P. L. C. Carter retires, receiving a gratuity.

INDIAN MEDICAL SERVICE.

Major-General W. H. Ogilvie has been appointed to officiate as Director of Medical Services in India during the absence on leave of Major-General O. L. Robinson.

Major J. A. Manifold has taken up duty as Assistant Director of Hygiene and Pathology at Quetta.

TERRITORIAL ARMY.

ROYAL ARMY MEDICAL CORPS.

Major O. H. Mavor (late R.A.M.C., T.A.) to be Major supernumerary for service with Medical Unit, Glasgow University, Senior Division O.T.C., with precedence as from October 19th, 1923.

Captain L. W. Matthews to be Major.

Lieutenant H. W. M. Williams resigns his commission.

Lieutenant J. R. Wheeler (late R.F.A. Spec. Res.) and J. H. Strahan to be Lieutenants supernumerary for service with Medical Unit, Belfast University, Senior Division O.T.C.

Lieutenant F. T. Birkinshaw (late R. Warwick R.) to be Lieutenant, with precedence as from August 31st, 1925.

J. S. M. Connell (late Captain, Special List) to be Lieutenant.

VACANCIES.

BIRMINGHAM AND MIDLAND HOMOEOPATHIC HOSPITAL AND DISPENSARY.—(1) Honorary Anaesthetist. (2) Honorary Consulting Ophthalmologist. (3) Honorary Dental Surgeon.

EXETER: ROYAL DEVON AND EXETER HOSPITAL.—House-Physician (male). Salary at the rate of £140 per annum.

HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, Brompton, S.W.3.—House-Physician. Honorarium £59 for six months.

HOVE: CARBURTON MEMORIAL HOSPITAL.—Resident Medical Officer (male, unmarried). Salary £150 per annum.

HUDDERSFIELD COUNTY BOROUGH.—Resident Medical Officer at the Bradley Wood Sanatorium for Pulmonary and Surgical Tuberculosis. Salary at the rate of £500 per annum.

HYDE BOROUGH.—Assistant Medical Officer of Health (part-time). Salary £300 per annum.

LANCASHIRE ASYLUMS BOARD, Preston.—Deputy Medical Superintendent at (*a*) County Medical Hospital, Lancaster; (*b*) County Mental Hospital, Rainhill. Salary at the rate of £600 per annum, rising to £700.

LEEDS CITY.—Assistant Medical Officer of Health for Maternity and Child Welfare. Salary £800 per annum.

MANCHESTER: ANCOATS HOSPITAL.—House-Physician. Salary £100 per annum.

METROPOLITAN ASYLUMS BOARD.—Second Assistant Medical Officer in the Mental Hospitals Service. Salary £550 per annum.

NEWPORT (MON.): ROYAL GWENT HOSPITAL.—House-Surgeon (male). Salary £125 per annum.

PLAISTOW FEVER HOSPITAL.—Second Assistant Medical Officer (male). Salary £300 per annum, including bonus, at present approximately £100 per annum.

SOUTHWARK METROPOLITAN BOROUGH.—Lady Assistant Medical Officer of Health (unmarried). Salary £600 per annum.

SUDAN GOVERNMENT.—Two Medical Officers for the Sudan Medical Service (unmarried). Pay £E.720 per annum, rising to £E.1,200.

UNIVERSITY COLLEGE HOSPITAL, Gower Street, W.C.1.—Honorary Physician in the Children's Department.

WARRINGTON INFIRMARY AND DISPENSARY.—Junior House-Surgeon (male, unmarried). Salary £175 per annum, rising £25 after six months.

WEST LONDON HOSPITAL, Hammersmith Road, W.6.—(1) Honorary Surgeon to the Throat, Nose, and Ear Department. (2) Honorary Obstetric Registrar.

CERTIFYING FACTORY SURGEON.— ppointment is announced: Downham Market to the Chief Inspector of Factories, Home

This list of vacancies is compiled from our advertisement columns, where full particulars will be found. To ensure notice in this column advertisements must be received not later than the first post on Tuesday morning.

APPOINTMENTS.

HARTLEY, James N. J., O.B.E., M.B., Ch.B., F.R.C.S., Honorary Surgeon to the Cumberland Infirmary, Carlisle, vice C. B. Paul, F.R.C.S.Edin.

MCDONALD, Niel, M.B., Ch.B.Manch., M.R.C.S., L.R.C.P., Anaesthetist to the Hospital for Sick Children, Great Ormond Street, W.C.1.

QUEEN CHARLOTTE'S MATERNITY HOSPITAL, Marylebone Road, N.W.1.—*Senior Resident Medical Officer:* A. V. Clemmey, M.B., Ch.B., M.R.C.S., L.R.C.P. *Assistant Resident Medical Officer:* W. N. Chisholm, M.B., Ch.B.

CERTIFYING FACTORY SURGEONS.—E. H. Heaton, M.R.C.S., L.R.C.P.Lond., for the Clacton-on-Sea District, co. Essex; J. G. B. Shand, M.B.Edin., for the Woolpit District, co. Suffolk.

DIARY OF SOCIETIES AND LECTURES.

ROYAL SOCIETY OF MEDICINE.

Sections of Comparative Medicine and Tropical Diseases and Parasitology.—Wed., 5.30 p.m., Special Joint Discussion: Trypanosomiasis in Man and Animals; to be opened by Dr. W. H. Andrews, Dr. J. Gordon Thomson, Mr. A. L. Sheather, and Dr. P. Manson-Bahr.

Section of Surgery.—Wed., 8.30 p.m., Discussion: Abdominal Tubercle. Openers: Mr. H. W. Carson and Mr. V. Zachary Cope (Surgery), Dr. Maurice Cassidy (Medicine).

NORTH-EAST LONDON CLINICAL SOCIETY, Prince of Wales's General Hospital, N.15.—Wed., 4.15 p.m., Discussion: Puerperal Sepsis. Speakers: Messrs. A. E. Giles, A. Goodwin, and T. H. C. Benians, and Dr. D. Kirkhope. Tea, 4 p.m.

POST-GRADUATE COURSES AND LECTURES.

POST-GRADUATE HOSTEL, Imperial Hotel, Russell Square, W.C.1.—Tues., 9 p.m., Address on Lord Lister by "One who knew him." Thurs., 9 p.m., Imperfect Descent of the Testis.

ROYAL NORTHERN HOSPITAL, Holloway Road, N.—Tues., 3.15 p.m., Gall Stones.

WEST LONDON HOSPITAL POST-GRADUATE COLLEGE, Hammersmith, W.6.—Mon., 10 a.m. to 1 p.m., Genito-urinary Operations, Skin Department, Surgical Ward Visit, [illegible]s; 2 p.m., Surgical Wards, Gynaecologic[illegible]es, 10 a.m. to 1 p.m., Lecture on Clinical [illegible] Venereal Diseases and Chest Cases; 2 p.[illegible] Nose, and Ear Department. Wed., 10 a.m [illegible] Out-patients; Medical Wards, Demonstration in Medical Pathology; 2 p.m., Surgical Wards, Eye Department. Thurs., 10 a.m., [illegible]; 2 p.m., Eye and Genito-urinary Department [illegible] Wards. Fri., 10 a.m. to 1 p.m., Gynaecol[illegible] Dental, and Electrical Departments, Lecture on Modern Methods in Medicine; 2 p.m., Throat, Nose, a[illegible]30 a.m. to 1 p.m., Bacterial Therapy and [illegible]at, Nose, and Ear Operations. Daily at 2 [illegible] Out-patients and Operations.

CURRENT NOTES.

A Medical Visit to Jamaica.

THE members of the Edinburgh and Leith Division, on learning that their past chairman intended to visit Jamaica, asked him to convey their greetings to the Jamaica Branch. Dr. Keppie Paterson accordingly fulfilled the request by calling on Dr. Strathairn, the honorary secretary, and afterwards received a call from Dr. Gifford, the president. Both were Edinburgh graduates and much friendly conversation resulted. Dr. Paterson was most agreeably received, and the secretary invited him to accompany him on his health duties to the west of the island, where a typhoid epidemic had broken out and where many were being inoculated against it. It was a motor run of about 160 miles through lovely scenery, including difficult roads with corkscrew turnings on the sides of the mountains. Dr. Paterson obtained much interesting information about the country, the people, and their diseases. He afterwards visited the general, maternity, leper, and the Nuttall hospitals, meeting the medical men and receiving much friendly attention. When reporting to the Division on his return, he drew attention to some of the more interesting points from the medical aspect. Ankylostomiasis is very common, and the Rockefeller Commission is doing excellent work in fighting it. Rickets is unknown in the island, and accordingly there are no rachitic pelves to complicate labour, though justo minor cases are met with. There is an amazing amount of albuminuria in pregnancy: 160 cases out of 860 admitted in a year into the Maternity Hospital, and of these 8 developed eclampsia. This large incidence of albuminuria is thought to be due to the prevalence of malaria; many cases clear up in ten days. Venereal disease is very common; a careful estimate is that 50 per cent. of the population are affected, and of these 17 per cent. are syphilitic. There are many cases of bad stricture. Appendicitis is rare, possibly owing to the large amount of fruit and vegetables in the dietary and to the position adopted in defaecation. Volvulus is common. Pneumonia is rare. Exophthalmic goitre does not exist. Rheumatism is not common. At the Leper Hospital, with over a hundred cases, they have discarded the hypodermic treatment and give a preparation of chaulmoogra oil in capsule by the mouth. It was evidently a most interesting trip, medically and otherwise. The interchange of courtesies between the home Branch and this oversea Branch of the British Medical Association added greatly to the pleasure and the benefit of the traveller, and Dr. Keppie Paterson's example might well be followed by others.

Undesirable Publicity.

A Chicago publishing firm issues a book called the *Red Book of Eye, Ear, Nose and Throat Specialists*, and a periodical called the *Eye, Ear, Nose and Throat Monthly*. In an offer which is being made to some of the eye, ear, nose, and throat specialists in this country the publishers state that all those who pay seven dollars for the directory will have the privilege of seeing their names in display type and receiving a copy of the periodical for two years. It is to be hoped that practitioners in this country who may have been approached by this firm will refuse to allow their names to appear in a directory which is obviously commercial in character, and to which strong exception is taken by the American Medical Association.

Subscriptions for 1927.

Members of the British Medical Association are reminded that subscriptions fall due on January 1st in each year, and that if each member on receiving an application for his or her subscription from the Head Office will send the amount to the Financial Secretary without delay the work of the office will be very considerably lightened. Members are also reminded of the claims of charity, to which reference was made in a leading article in last week's JOURNAL. The amounts at the disposal of those who administer medical benevolence are altogether insufficient to deal adequately with the cases needing help, and the British Medical Association Charities Fund was formed in order to assist. Contributions are urgently needed, and all members are asked to add to their next payment a sum for the credit of that Fund.

Meetings of Branches and Divisions.

BOMBAY BRANCH.

A GENERAL meeting of the Bombay Branch was held on October 26th, 1926, at the Pathological Laboratory, G.M. College, Bombay, when General HOOTAN, C.I.E., I.M.S., Surgeon-General with the Government of Bombay, who had specially come from Poona on that occasion, was voted to the chair. The following officers were elected:

President, Dr. R. Row, D.Sc. *Vice-Presidents*, Colonel Mackie, M.D., I.M.S., and Mr. A. K. Dalal, F.R.C.S. *Joint Honorary Secretaries*, Dr. F. D. Bana, D.P.H., D.T.M. and H., and Dr. B. Yodh, D.T.M.

General HOOTAN then called on Dr. R. Row as the president to take his rightful place as chairman of the meeting, which the latter did amid applause. He thanked the members for doing him the honour of electing him as the president for the local Branch of the British Medical Association, and said that he had undertaken the work solely from regard for the parent Association and from his love of professional and scientific work. He proposed to ban politics and meant to promote scientific and professional harmony, and in this he invited his colleagues to participate in full by lending their help and co-operation so as to make the meetings successful; it was on them that much depended for the future well-being and progress of the Branch which he had tried to resuscitate. He next expressed regret on behalf of the Branch officially at the sad death of the late secretary, Mr. D. R. Bardi, F.R.C.S., who had worked for so many years as honorary secretary and treasurer. Dr. W. NUNAN then moved that a letter of sympathy be written to the widow and family; this was seconded by Dr. D'MONTE and carried unanimously. The PRESIDENT next called the attention of members to the circular letter from the secretary of the Bombay Committee for Combating Venereal Diseases, calling for co-operation of the Branch in welcoming Dr. Lees and Mrs. Rolfe as delegates of the British Social Hygiene Council next cold weather. A committee was appointed to deal with this matter.

Lieut.-Colonel MCCOMBIE YOUNG, I.M.S., read a paper on sandflies, demonstrating the principal phlebotomus found in Bombay,

and describing a new one found by him and Captain Chalam which might prove to be a variety so far undescribed. The lecture was very interesting and the epidiascope very instructive. A vote of thanks was accorded from the chair to the lecturer.

Major-General HOOTAN, I.M.S., *in response to the President's* suggestion, addressed a few words of advice. He said that in his time he had been responsible for inaugurating two medical societies, one in Poona and one in Khathiawar, and both were doing well in professional work. He did not therefore see any reason why the Bombay Branch of the British Medical Association should not outstay any of them and hold more frequent clinical meetings where members as well as co-opted young members should meet more often than at present to discuss scientific and professional work. As for the argument that Bombay members were fully busy in their practices, he would suggest co-option of associate members for the newly qualified practitioners, and also for those not registrable in the United Kingdom—that is, the I.M.D. and the S.A.S. class, who had done so well in the late war. In reply to this suggestion Dr. ROW said he would communicate with the headquarters of the Association in London, asking for its consent.

NORTHERN COUNTIES OF SCOTLAND BRANCH.

A MEETING of the Northern Counties of Scotland Branch was held in the Northern Infirmary, Inverness, on December 3rd, 1926, when Dr. E. K. MACKENZIE was in the chair and thirty-one members attended. The meeting took the form of a clinical demonstration given by members of the staff of the Infirmary. Dr. J. W. MACKENZIE first read a very full paper on aural and nasal discharges. Dr. ALEXANDER REID followed with the demonstration of three cases of rheumatoid arthritis and gave some account of the nature of the disease, pointing out the complete difference between this disease and osteo-arthritis, illustrating it by skiagrams of the joints of the patients he had demonstrated. He also made some remarks on the treatment of the disease. Lastly, Dr. M. MACFADYEN demonstrated a series of skiagrams of fractures seen in the electrical department of the Infirmary during the previous six months. Tea was served afterwards by the nursing staff of the Infirmary.

NORTH OF ENGLAND BRANCH: CLEVELAND DIVISION.

A VERY well attended meeting of the Cleveland Division was held at North Ormesby Hospital on the evening of December 16th, 1926. The meeting was addressed by Dr. KNYVETT GORDON of London, who chose for his subject "The diagnosis and treatment of anaemia and allied conditions." The lecture, which was illustrated with an epidiascope, was listened to with great interest and attention, and the subsequent discussion and questions were answered by the speaker. At the close a hearty vote of thanks, proposed by Dr. T. M. BODY, was accorded to Dr. GORDON. The attendance was the largest of recent years at an addressed meeting.

SOUTH MIDLAND BRANCH.

THE autumnal meeting of the South Midland Branch was held at the Northampton General Hospital on November 25th, 1926, when Dr. F. S. LLOYD, president, was in the chair.

Mr. WALTER SALISBURY, M.S., F.R.C.S. (Northampton), read a paper on "Uterine haemorrhage." He first dealt with those cases which were associated with physical signs, explaining the mechanism of the bleeding in the different types of growth and inflammation, and emphasizing various points of interest in connexion with their diagnosis and treatment. Sim's speculum might with great advantage be used more frequently than it was. He much preferred subtotal to total hysterectomy for fibroids unless the cervix was definitely unhealthy. He regretted that such a large proportion of women with carcinoma of the cervix were first seen when it was too late to do the radical operation or to do it with the hope that the cure would be permanent. Chronic metritis and its pathology were next described. There was severe and prolonged menstrual loss, usually dating from a confinement, and examination revealed a symmetrically enlarged hard uterus. Drugs and curettage were useless, but the patient could be cured by hysterectomy or often by radium. The lecturer discussed cases of uterine haemorrhage in which there were no physical signs. Several different organs were concerned. The endometrium was the source of the bleeding, the uterine muscle the tap which controlled it, the ovaries the glands which initiated and governed menstruation, and the thyroid had a stimulating effect on the ovaries. The pituitary and adrenal glands, the sympathetic nervous system, and the brain all had an influence on the menstrual function. In very rare cases the blood was at fault. *An attempt should be made to find out where the fault lay in* any particular case. Epimenorrhoea, or too frequent menstruation, was due to overactivity of the ovaries, and curettage was useless for it. Menorrhagia in young girls was sometimes due to hyperthyroidism and might be benefited by *x*-ray treatment of the thyroid. In simple functional menorrhagia general hygienic treatment was the most effective. Menopausal haemorrhage, if growth had been excluded and drugs failed, could usually be cured by *radium*. Post-menopausal haemorrhage was almost invariably due to growth, and if the cervix was healthy a diagnostic curettage should be done without delay.

The President, Dr. LLOYD, in declaring the paper open for discussion, congratulated the speaker on the very excellent paper. He agreed as to the importance of passing a speculum, especially to exclude cervical polyp. He also discussed prolonged menstruation, and instanced a case in which menstruation persisted until the age of nearly 80. Mr. HOLMAN spoke as to the ease with which one might overlook a small cervical polypus. He agreed that subtotal hysterectomy was much preferable to panhysterectomy for fibroids as a rule. He instanced two cases possibly due to overaction of the thyroid, and discussed papilloma as a cause of haemorrhage. Mr. BARNES spoke in defence of calcium lactate, which Mr. Salisbury had said was unworthy of a place in the *Pharmacopoeia*. Calcium lactate had a definite value in cases of hypersensitiveness to certain toxins, if not for haemorrhage. Dr. HENDERSON advised the administration of calcium lactate combined with parathyroid. Dr. SHAW gave details of a case of uterine haemorrhage in a young girl whose life was saved by *administration of corpus luteum*. Dr. GREENFIELD said that some cases of uterine haemorrhage were due to hypothyroidism. Young girls sometimes benefited by the administration of thyroid.

After tea had been served Mr. SALISBURY demonstrated the sparklet apparatus for inflating the Fallopian tubes in certain cases of sterility. It showed whether either or both of the tubes were patent. In many cases where they were blocked the adhesions at the fimbrial end were of a filmy nature and gave way under the pressure of the gas, for the pressure of the inflating gas suddenly fell and at the same moment the sound of the escaping gas in the abdomen could be heard with a stethoscope. The method was therefore of value in treatment, and could be repeated every three to six months. It only took a few minutes and required no anaesthetic, except perhaps the first time.

A very excellent collection of specimens, numbering seventeen in all, was then exhibited; they were shown by Mr. SALISBURY, Mr. HOLMAN, Dr. TOLPUTT, and Mr. BARNES.

Association Notices.

PROPOSED DOVER, FOLKESTONE, AND ASHFORD DIVISIONS.

NOTICE is hereby given to all concerned of the following proposals made by Kent Branch:

That the existing Dover and Folkestone Division of the Kent Branch be discontinued, and that new Divisions of the Branch, with areas as follows, be formed:

Dover Division.—The municipal boroughs of Deal, Dover, and Sandwich, the urban district of Walmer, the rural districts of Eastry and Dover.

Folkestone Division.—The municipal boroughs of Folkestone and Hythe, the urban districts of Sandgate and Cheriton, the rural district of Elham.

Ashford Division.—The municipal borough and rural district of Tenterden (to be transferred from Maidstone Division), the municipal boroughs of Lydd and New Romney, the urban district of Ashford, the rural districts of East Ashford, Romney Marsh, and West Ashford.

Written notice of the proposals has been given to all the existing bodies concerned, and the matter will be determined in due course by the Council. Any member affected by the proposed change, and objecting thereto, is requested to write, giving reasons, to the Medical Secretary, British Medical Association House, Tavistock Square, London, W.C.1, to reach him not later than February 8th, 1927.

BRANCH AND DIVISION MEETINGS TO BE HELD:

BIRMINGHAM BRANCH: WEST BROMWICH DIVISION.—The annual meeting of the West Bromwich Division will be held at the District Hospital, West Bromwich, on Tuesday, January 11th, at 3 p.m. Agenda: Résumé by retiring chairman of the work of the Division during 1926; election of officers for 1927; programme for 1927; alteration of Rule 12 (1)—the Executive Committee suggests that the rule be altered to read: "Ordinary meetings of the Division shall be held during the months of January, April, June, and October (three meetings in West Bromwich, one meeting in Smethwick)"; formation of local Hospitals Committee; medical charities; chairman's address.

BORDER COUNTIES BRANCH: DUMFRIES AND GALLOWAY DIVISION.—The next meeting of the Dumfries and Galloway Division will be held in the Royal Infirmary, Dumfries, on Thursday, January 13th, at 3.30 p.m., when, in addition to the routine business, an important report on the hospital accommodation of the area will be considered.

GLASGOW AND WEST OF SCOTLAND BRANCH: LANARKSHIRE DIVISION.—A meeting of the Lanarkshire Division will be held at the Masonic Hall, Hamilton, on Tuesday, January 11th, at 8.30 p.m. Dr. John Glaister will read a paper on "The medical man in the witness-box."

METROPOLITAN COUNTIES BRANCH: CITY DIVISION.—The next clinical meeting of the City Division will be held at the Metropolitan Hospital on Friday afternoon, January 14th, at 4.15, when Dr. Norman Hill will show cases. Tea at 4 o'clock.

METROPOLITAN COUNTIES BRANCH: FINCHLEY DIVISION.—A meeting of the Finchley Division will be held at the Finchley Memorial Hospital on Tuesday, January 11th, at 8.45 p.m. Agenda: A clinical case to be shown by Dr. ORR; address by Dr. George Riddoch on "Some sequelae of encephalitis lethargica."

METROPOLITAN COUNTIES BRANCH: HAMPSTEAD DIVISION.—A Divisional meeting will be held at Hampstead General Hospital on Thursday, January 13th, at 8.30 p.m. An address will be given by Dr. W. J. Adie on "Some fits and seizures." Coffee will be served.

METROPOLITAN COUNTIES BRANCH: KENSINGTON DIVISION.—A ball, arranged by the Kensington Division in aid of the Royal Medical Benevolent Fund, will be held at the Kensington Town Hall on Tuesday, January 11th, from 9 to 2 o'clock. The ball is under the patronage of H.R.H. the Princess Louise Duchess of Argyll. The Clifford Essex Band will play. The price of tickets is one guinea each or six for five guineas; they may be obtained from the Honorary Secretary, 20, Upper Phillimore Place, Kensington, or from any member of the Executive Committee.

METROPOLITAN COUNTIES BRANCH: LEWISHAM DIVISION.—A meeting of the Lewisham Division will be held at the Town Hall, Catford, S.E.6, on Tuesday, January 18th, at 8.45 p.m. Mr. C. A. Joll, F.R.C.S., will give an address on "The diagnosis and treatment of diseases of the gall bladder and bile ducts."

METROPOLITAN COUNTIES BRANCH: NORTH MIDDLESEX DIVISION.—At the meeting of the North Middlesex Division to be held on Wednesday, January 26th, a discussion on insulin will be opened by Dr. G. Grant Macdonald.

METROPOLITAN COUNTIES BRANCH: ST. PANCRAS DIVISION.—At the meeting of the St. Pancras Division to be held at the British Medical Association House, Tavistock Square, W.C., on Tuesday, January 11th, at 9 p.m., Dr. H. C. Cameron will give an address on "Nursery psychotherapeutics."

METROPOLITAN COUNTIES BRANCH: WEST MIDDLESEX DIVISION.—A meeting of the West Middlesex Division will be held on Thursday, January 13th, at 8.30 p.m., at King Edward Memorial Hospital, Mattock Lane, Ealing. Mr. Gordon Bryan has kindly consented to give an address on "Injuries of the knee." A discussion will follow.

NORTH OF ENGLAND BRANCH.—A scientific meeting of the North of England Branch will be held at the Royal Victoria Infirmary, Newcastle-on-Tyne, on Thursday, January 20th—2.15 p.m., Sir Thomas Oliver: Heart disease and pregnancy; 2.45 p.m., Mr. J. B. McDougall: Occupational therapy as an adjunct to the treatment of pulmonary tuberculosis; 3.15 p.m., Mr. Glen Davison: The N.C.P. method of dieting the sick infant; 3.45 p.m., tea; 4 p.m., Mr. Grey Turner: Difficulty in swallowing; 4.30 p.m., Dr. Whately Davidson: X-ray diagnosis of disorders of the alimentary tract.

NORTH OF ENGLAND BRANCH: BISHOP AUCKLAND DIVISION.—At the meeting of the Bishop Auckland Division arranged for Friday, January 28th, Dr. A. T. Paterson (Durham) will lecture on "Some common ailments of the eye."

NORTH OF ENGLAND BRANCH: SUNDERLAND DIVISION.—The following scientific lectures have been arranged by the Sunderland Division to be held at the Royal at 8.15 p.m. on the dates indicated: February on "Pleural effusion"; March 21st, Mr. F. C. Ayerst on "Deformities"; April 18th, Dr. E. Farquhar Murray on "Some modern aspects of midwifery and gynaecology"; May 16th, Dr. George Hall on "Encephalitis lethargica and its sequelae."

SOUTHERN BRANCH: PORTSMOUTH DIVISION.—The Executive Committee of the Portsmouth Division has arranged a *souper dansant* to be held at the Esplanade Assembly Rooms, Southsea, on Tuesday, January 11th. Dancing from 9 p.m. Tickets, 10s. each (including supper), can be obtained from the honorary secretary, Dr. H. H. Warren, Devonia, Goldsmith Avenue, Southsea. Tickets are limited to 300. Any profit will be devoted to medical charities. The next monthly meeting of the Division will be held at the Queen's Hotel, Southsea, on Thursday, January 13th, at 9.30 p.m. Supper will, as usual, be served at 9 o'clock precisely. At the conclusion of the business Dr. Thomas Beaton will give an address on "The recognition and management of the mental patient in general practice." Members who intend to be present at supper are particularly requested to notify the honorary secretary, Dr. H. H. Warren, by Monday, January 10th.

SURREY BRANCH: CROYDON DIVISION.—A meeting of the Croydon Division will be held at the Croydon General Hospital on Tuesday, January 25th, at 8.30 p.m. Sir Frank Colyer will give an address on "Dental sepsis in relation to other pathological conditions."

SURREY BRANCH: REIGATE DIVISION.—A meeting of the Reigate Division will be held at the East Surrey Hospital, Reigate, on Tuesday, January 11th, at 8.45 p.m. Dr. Stoddart will read a paper on "The certification of mental patients."

SUSSEX BRANCH: BRIGHTON DIVISION.—A meeting of the Brighton Division will be held at the Royal Sussex County Hospital, Brighton, on Wednesday, January 19th, at 3.45 p.m.

YORKSHIRE BRANCH: DEWSBURY DIVISION.—A meeting of the Dewsbury Division will be held at the Man and Saddle Restaurant, Dewsbury, on Tuesday, January 11th. Coffee served at 8.15 p.m. Dr. W. Macadam (Leeds) will read a paper on "Abdominal pain—its various types and their differentiation." Members from neighbouring Divisions will be welcome.

YORKSHIRE BRANCH: WAKEFIELD, PONTEFRACT, AND CASTLEFORD DIVISION.—A meeting of the Wakefield, Pontefract, and Castleford Division will be held at the Bull Restaurant, Westgate, Wakefield, on Thursday, January 13th, when Dr. T. W. Griffith, consulting physician, Leeds General Infirmary, will give a lecture on "The prevention of heart disease and the causes and treatment of irregular heart action." Supper at 7.45 *p.m.* (2s. 6d.) will precede the lecture.

Correspondence.

The General Practitioner and the Hospital.

SIR,—In his address to the members of the Stratford Division (SUPPLEMENT, December 25th, 1926, p. 257) Mr. H. S. Souttar, visualizing the future and acknowledging that there will be still a place in the sun for the general practitioner, advocates the large voluntary hospitals, and especially the teaching hospitals, as being most suitable for the purpose of consultation and post-graduate education, yet recommends those general practitioners who are desirous of continuing to treat their patients—removed to a hospital because of unsuitable home conditions—to use the municipal hospitals as being *the* place.

Now both groups of hospitals have resident medical staffs and visiting medical staffs. Both are equally suitable for purposes of consultation, for teaching students, and for post-graduate education, seeing that there is no exclusion from either on account of age, sex, or illness. The industrial and middle classes pay under contributory schemes in one case and through the rates and taxes in the other. Will Mr. Souttar be good enough to point out what it is exactly that renders it impossible for a large voluntary hospital or teaching hospital to provide beds for general practitioner use while the municipal hospitals are considered to be "just it"? He omitted to mention the reasons for this limitation.—I am, etc.,

Hove, Dec. 29th, 1926. E. ROWLAND FOTHERGILL.

Naval and Military Appointments.

ROYAL NAVAL MEDICAL SERVICE.

Surgeon Commanders A. R. Fisher to the *Britannia* for R.N. Sick Quarters, Dartmouth; B. P. Pick to the *President*, additional for three months' St.C. Colson to the *President*, additional for four course. The appointment of Surgeon Comman , O.B.E., to the *Marlborough* is cancelled.

CURRENT NOTES.

Some Work of the Week.

has been suggested that members of the British Medical sociation might be interested to have a short account of ne of the medico-political and kindred work which goes from week to week at headquarters, and an attempt will made to indicate the different methods by which the erests of the profession, collective and individual, are ed for.

During the week beginning January 3rd three com-ittees or subcommittees were held. The first, on January , was a Building Committee, which is considering the elopments of the Association's premises, with particular erence to those arising from the falling in of the leases the houses leading down to the gates of the new House. is impossible from the nature of the case to do more n mention the work of a committee whose main duty it to look forward to the future and try to gauge the bable development of the housing needs of the Asso-tion. On the same afternoon the Propaganda Sub-mittee had before it much interesting information as to ways in which the attractions of the Association are put fore potential members, and the results. The sub-mittee was informed, for example, of the visits of mbers of the central staff to Divisions, etc., all over the ntry, and also similar visits of members of Council and nding Committees. Included in these visits were two dresses by the Medical Secretary to the students of aring Cross and London Hospitals, at which it is believed d work was done. The other meetings were all either vision meetings, at which special propaganda work was ne, or the not less valuable social functions at which mbers of the staff and members of central bodies come o contact with the local members of the profession. list of the Divisions which are apparently unorganized inactive was carefully considered and an attempt made find out why the members in these areas were without facilities they have a right to expect. The subcommittee ne to the conclusion that, with few exceptions, local rtia was chiefly to blame. The arrangements for the stings Lecture by Sir Berkeley Moynihan on "Cancer d how to fight it" in the Great Hall of the Association's use on the evening of January 24th were considered, and subcommittee was glad to hear that the demand for tickets was very great. The chair will be taken at 8 p.m. by the Minister of Health.

On January 6th the Charities Committee met and settled a form of appeal which is shortly to be sent out to all Divisions, calling upon them to take their part in the effort to which the Association is committed to obtain increased support for the medical charities. This committee found that in making such an appeal there were many possibilities of overlapping and misunderstanding which can probably only be cleared up after a year or two's experience.

The members of the staff have dealt with a good many applications by individual members with respect to the obtaining of professional work; queries as to the R.A.M.C. as a career, which can now be cordially recommended to young men of the right type; post-graduate work and accommodation; coaching for examinations; special qualifications in surgery and ophthalmology; practice in France and Italy; homes for patients. The last named subject is one on which much useful work is done in the head office, and a great many members now apply for advice as to the best place to send particular cases, especially those whose means are not very adequate. There have been a good many inquiries about a recently much advertised treatment for epilepsy which comes from Germany. In addition there were many questions arising as to the suitability of advertisements offered for insertion in the JOURNAL where professional questions were involved, and these were cleared up, generally after reference to the secretaries of Divisions.

The Malaya Branch.

Commencing with the first number of the present year, the *Malayan Medical Journal* becomes the official organ of the Malaya Branch of the British Medical Association, under the editorship-in-chief of Dr. G. H. Macalister, principal of the College of Medicine in Singapore, with Professor A. Neave Kingsbury as associate editor, and a number of regional editors. Under this new arrangement each member of the Malayan Branch will receive the journal quarterly. The December issue of the *Journal* gives a short history of medical journalism in Malaya, based on an account in the *Transactions* of the Malayan Branch, 1922-23, compiled by Dr. J. W. Scharff, honorary secretary of the Branch. The first periodical published appeared in 1892, under the title of the *Journal of the Straits Medical Association*, but, after the issue of five numbers, it ceased to exist in 1894, when the Straits Medical Association was affiliated with the British Medical Association. After an attempt in 1903 to revive it under the title of the *Journal of the Malaya Branch of the*

British Medical Association there was an interval until 1911, when the *Malaya Medical Journal* was established and lasted for two years. The present periodical, of which four quarterly numbers have now appeared, has been under the editorial direction of Dr. T. S. Macaulay. It is announced that the next annual meeting of the Branch will be held at the Institute of Medical Research in Kuala Lumpur, from April 15th to 17th. We wish the *Malayan Medical Journal* a long life of usefulness and prosperity under the new arrangements made for its publication.

At a meeting of the Malaya Branch Council on November 29th, 1926, the arrangements for Sir Ronald Ross's approaching visit were discussed, and it was agreed that the Branch should give 100 dollars to Sir Ronald Ross for his Institute or other scientific purposes. The treasurer stated that the Branch had contributed 226 dollars to the Royal Medical Benevolent Fund. Sir Ronald Ross arrived at Singapore on December 4th, as the guest of the Malaya Branch, by which he was entertained at dinner the same evening. The President, Dr. A. L. Hoops, took the chair, and, in welcoming Sir Ronald Ross, gave an account of the chief incidents in his career, with special reference to the benefits Malaya had gained from his discoveries about the malaria parasite. Sir Ronald Ross, in his reply, congratulated Malaya on its active work in mosquito destruction and the good results that had followed. Sir Malcolm Watson proposed the health of the other guests, including Professor Bostock Hill, who, in his reply, mentioned that he had been a member of the Association for more than fifty years. He had held office since the passing of the Public Health Act in 1875, and had seen the whole evolution of the sanitary ideal, which concerned itself at first with environment, and only became more centred on the individual at the beginning of the present century. Referring to the main purpose of his visit to the Straits Settlements—namely, to confer on the subject of social hygiene, Professor Hill said he had been given every opportunity for investigation, and had come to the conclusion that, though the problem in Singapore was very difficult, yet a very excellent start had been made, and there was every reason to believe that considerable improvement would soon follow. The health work in Malaya generally compared favourably with any he had ever known. A reception was held at the King Edward VII College of Medicine on December 7th, when Sir Ronald Ross unveiled the portrait of Dr. G. A. Finlayson, one of the first lecturers of the College, and gave an address on the history of malaria research, illustrated by lantern slides made from photographs of the original specimens collected in 1897.

Membership of the Association.

On December 23rd, 1926, the membership of the British Medical Association was 32,354, an increase of 1,825 on the total at the corresponding date in 1925.

Portsmouth Division.

In response to an appeal from its Executive Committee, the sum of £103 17s. 6d. was subscribed in a few days by members of the Portsmouth Division of the British Medical Association towards a "Remembrance Fund" organized at Christmas by the *Portsmouth Evening News* to afford relief to distressing cases amongst the men of the old Portsmouth Battalion and their families. The editor of the *Evening News* writes: "The medical contribution is most generous and we are very grateful for it."

The Half-yearly Indexes.

The usual half-yearly indexes to the JOURNAL and to the SUPPLEMENT and EPITOME have been prepared and will be published shortly; they will, however, not be issued with all copies of the JOURNAL, but only to those readers who ask for them. Any member or subscriber who desires to have one or all of the indexes can obtain what he wants, post free, by sending a post-card notifying his desire to the Financial Secretary and Business Manager, British Medical Association House, Tavistock Square, W.C.1. Those wishing to receive the indexes regularly as published should intimate this desire.

Association Notices.

SALISBURY AND SWINDON DIVISIONS.

THE following change has been made by the Council, and takes effect as from the date of publication of this notice:

That the Civil Parish of Ludgershall be transferred from the Swindon to the Salisbury Division of the Wiltshire Branch.

BRANCH AND DIVISION MEETINGS TO BE HELD.

BIRMINGHAM BRANCH.—The third ordinary meeting of the Birmingham Branch will be held at the Birmingham Medical Institute on Thursday, January 20th, at 3.30 p.m., with the President, Dr. H. G. Dain, in the chair. A paper on "Intrathoracic tumours" will be read by Dr. Douglas Stanley, and at the end of the meeting tea will be provided by the President.

METROPOLITAN COUNTIES BRANCH: LEWISHAM DIVISION.—A meeting of the Lewisham Division will be held at the Town Hall, Catford, S.E.6, on Tuesday, January 18th, at 8.45 p.m. Mr. C. A. Joll, F.R.C.S., will give an address on "The diagnosis and treatment of diseases of the gall bladder and bile ducts."

METROPOLITAN COUNTIES BRANCH: NORTH MIDDLESEX DIVISION.—At the meeting of the North Middlesex Division to be held on Wednesday, January 26th, a discussion on *insulin will be opened* by Dr. G. Grant Macdonald.

METROPOLITAN COUNTIES BRANCH: WILLESDEN DIVISION.—A meeting of the Willesden Division will be held at the Willesden General Hospital, Harlesden Road, on Wednesday, January 19th, at 9 p.m. Agenda: Correspondence, etc.; report of Executive Committee on letter from Willesden General Hospital; resolution of last meeting with regard to minimum fees for attendance and treatment of dependants of the insured, and the scale of fees for emergency treatments of dependants.

MIDLAND BRANCH: LEICESTER AND RUTLAND DIVISION.—At the meeting of the Leicester and Rutland Division to be held at the Medical Club, Bond Street, Leicester, on Friday, January 21st at 8.45 p.m., a British Medical Association Lecture will be given by Mr. H. S. Souttar, M.Ch., F.R.C.S., on "The clinical aspect of gastric and duodenal ulcers."

NORTH OF ENGLAND BRANCH.—*A scientific meeting of the North of England Branch will be held at the Royal Victoria Infirmary, Newcastle-upon-Tyne, on Thursday, January 20th—2.15 p.m., Sir* [illegible] sease and pregnancy; 2.45 p.m., Mr. J. F. [illegible] therapy as an adjunct to the treatment of pulmonary tuberculosis; 3.15 p.m., Mr. Glen Davison: The N.C.P. method of dieting the sick infant; 3.45 p.m., tea; 4 p.m., Mr. Grey Turner: Difficulty in swallowing; 4.30 p.m., Dr. Whatel Davidson: *X-ray diagnosis of disorders of the alimentary tract.*

NORTH OF ENGLAND BRANCH: BISHOP AUCKLAND DIVISION.—At the meeting of the Bishop Auckland Division arranged for Friday, January 28th, Dr. A. T. Paterson (Durham) will lecture on "Some common ailments of the eye."

NORTH OF ENGLAND BRANCH: SUNDERLAND DIVISION.—The following scientific lectures have been arranged at meetings of the Sunderland Division to be held at the Royal Infirmary, Sunderland, at 8.15 p.m. *on the dates indicated*: February 16th, Dr. A. Parkin on "Pleural effusion"; March 16th, Mr. F. C. Pybus on "Deformities"; April 20th, Dr. E. Farquhar Murray on "Some modern aspects of midwifery and gynaecology"; May 18th, Dr. George Hall on "Encephalitis lethargica and its sequelae."

NORTH LANCASHIRE AND SOUTH WESTMORLAND BRANCH.—A combined Branch and Divisional meeting will be held in Kendal on January 20th. Professor Fletcher Shaw will deliver an address on "Lower *abdominal* pain in women." Members wishing to attend the Divisional dinner at 7.30 p.m. are requested to notify Dr. Balsillie, Kendal.

OXFORD AND READING BRANCH: OXFORD DIVISION.—A meeting of the Oxford Division will be held at the Radcliffe Infirmary on Wednesday, January 26th, at 2.30 p.m. Mr. Hugh Whitelocke will read a paper entitled "Impressions of American surgery."

SOUTH WALES AND MONMOUTHSHIRE BRANCH: CARDIFF DIVISION.—At the meeting of the Cardiff Division to be held at the Engineers' Institute, Cardiff, on Wednesday afternoon, January 26th, Professor W. E. Dixon, M.D., F.R.S., will give a British Medical Association Lecture on "The trend of thought in modern therapy."

SOUTHERN BRANCH: JERSEY DIVISION.—The following programme has been arranged by the Jersey Division: January 20th, paper by Mr. A. S. Ferguson, F.R.C.S., on epistaxis; February 17th, paper by Lieut.-Colonel P. J. Marett on tubercle; March 17th, paper by Dr. H. Marett Tims; April 21st, paper by Mr. A. Le Sueur, M.R.C.V.S.; May 19th, paper by Mr. A. S. Blackwell, F.R.C.S., on anaesthetics; June 16th, paper by Mr. J. S. Price, L.D.S. Meetings are held at 8.30 p.m. in the Committee Room of the General Hospital. Members having cases of interest are invited to show them at any of the meetings.

SUFFOLK BRANCH: NORTH SUFFOLK DIVISION.—A meeting of the North Suffolk Division will be held at the Lowestoft Hospital on Thursday, January 27th, at 4 p.m. Dr. Alfred Cox (Medical Secretary of the Association) will give an address on "The essentials of a medical organization." Non-members are *cordially invited*.

SURREY BRANCH: CROYDON DIVISION.—A meeting of the Croydon Division will be held at the Croydon General Hospital on Tuesday, January 25th, at 8.30 p.m. Sir Frank Colyer will give an address on "Dental sepsis in relation to other pathological conditions."

SUSSEX BRANCH: BRIGHTON DIVISION.—A meeting of the Brighton Division will be held at the Royal Sussex County Hospital, Brighton, on Wednesday, January 19th, at 3.45 p.m.

Meetings of Branches and Divisions.

ASSAM BRANCH: ASSAM VALLEY DIVISION.

A TWO-DAY meeting of the Assam Valley Division was held on October 9th and 10th, 1926, at the Berry White Medical School, Dibrugarh, Dr. D. P. WILLIAMS, the President of the Assam Branch, being in the chair. Dr. F. C. MCCONNIE contributed a paper on the sanitation of tea gardens, and Dr. F. W. O'CONNOR read a paper on sanitation and lines for tea garden coolies. The PRESIDENT also addressed the meeting on the subject of line drainage.

In the discussion Lieut.-Colonel GRAHAM, I.M.S., agreed that there had been a marked improvement in the health of tea-garden coolies, which reflected credit on the medical officers. He thought oral vaccines as a preventive of cholera were worth investigation. The PRESIDENT stated that he had a garden in which endemic pneumonia was causing a mortality of approximately 30 per cent. Drainage of the affected lines was instituted, and it was observed that no cases of pneumonia occurred in nineteen brick houses, whereas the old type of house still supplied its usual quota of patients. No apparent benefit had resulted from the usual prophylaxis of pneumonia, and the President added that he had heard from Sir Spencer Lister of the Johannesburg Research Institute that the usual prophylactic measures had similarly failed in endemic pneumonia occurring in the mining districts of South Africa. The disease was eventually controlled by an autogenous vaccine in South Africa, and Dr. Williams proposed to try this method. Dr. FOSTER considered that the line system described by the President was a great improvement, but it was necessary to allocate a suitable place for the collection of refuse from the houses to avoid blocking the line drains.

Dr. F. W. O'CONNOR referred to the importance of the infantile death rate as a prime factor in determining the health of any garden, especially where malaria was endemic. He believed that wherever the malaria incidence was high the pneumonia incidence and mortality were correspondingly great.

At the business meeting on October 10th the PRESIDENT announced that a rail ambulance had now been provided, and that negotiations were in progress to obtain a motor ambulance to take patients from Gauhati to Shillong. He was endeavouring to obtain a reduction in the cost of petrol for medical officers as he considered it essential for the proper fulfilment of their professional duties. It was agreed that the meeting-place for the next annual general meeting should be Haflong. The President entertained the members to dinner during the week-end.

CAPE OF GOOD HOPE (MIDLAND) BRANCH.

THE annual general meeting of the Cape of Good Hope (Midland) Branch was held in the Provincial Hospital on December 9th, 1926, when the President, Dr. ANDREW STEWART, took the chair.

The SECRETARY, in his annual report, indicated how, as a unit, the Branch had taken its share in redressing many evils which had arisen from time to time in the medico-political field. He referred to the visit of Dr. Alfred Cox and to its very happy sequel—the great measure of solidarity which had been achieved in cementing the profession into a strongly organized medical association. The Branch had assisted in the collection of information which resulted in the meeting of the Federal Council with the administrators of the Railway Sick Fund, upon which meeting hinged much in the interests of railway medical officers throughout the Union. Dr. Jabkoritz stressed the importance of Dr. Hugh Smith's having come to Port Elizabeth to deliver the first Medical Association lecture, this being a further milestone on the path of progress. In conclusion Dr. Jabkovitz, who had given six years' continuous secretarial service to the members of the profession in the area, whose interests he had most jealously guarded, and who was now resigning from office, thanked the retiring office-bearers and members of Council for their very hearty co-operation. He assured the new secretary that with such co-operation from the members of the new Council the work would be found most pleasant.

The following office-bearers were elected for 1927:

President, Dr. J. G. Muterer (Port Elizabeth). *President-Elect*, Dr. Karl Bremer (Graaff Reinet). *Vice-President*, Dr. N. Wilson (Port Elizabeth). *Honorary Secretary and Treasurer*, Dr Gordon Robson (Port Elizabeth). *Representative on Federal Council*, Dr. R M. Leith.

DORSET AND WEST HANTS BRANCH: BOURNEMOUTH DIVISION.

A MEETING of the Bournemouth Division was held, in conjunction with the Bournemouth Legal Society, on December 3rd, 1926, in St. Peter's Large Hall, when a discussion on criminal responsibility took place. Dr. EDWARDS was in the chair, and there were present sixty members of the Division and about fifty lawyers.

Criminal Responsibility.

Dr. HYLA GREVES opened the subject with a very interesting paper; he stated that from a medical point of view responsibility was very difficult to determine, while from a legal view the question was usually beyond doubt. He further went on to say that the plea of insanity was now governed by the answers to the questions given by the judges to the Commission after the famous M'Naghten case. Each case should be decided on its own merits by mental experts. It was not sufficient to determine whether a prisoner knew what he was doing and what the consequences would be; it was important to find out what was the state of the mind when the act was committed. Insanity was not the same as a disordered mind; it was more a loss of control of mental faculty. A man who committed a crime during a period of post-epileptic automatism could not be held responsible for any act which he committed, and the same applied to a person suffering from general paralysis. Delusions as a mark of insanity were very much overrated, but a person who committed a crime through a delusion from which he suffered should not be held responsible for it in a court of law. The speaker went on to say that in many cases where a criminal was of sound mind he came from a family where epilepsy and insanity were conspicuous; in other cases the commission of a crime might mark the period in a man's life when insanity first made its appearance. He was strongly of the opinion that instead of doctors having to give evidence in the witness-box on the state of the prisoner's mind, a panel of experts should investigate each individual case and make a report, as was done in other countries.

Mr. LEFROY said that the views of lawyers and doctors on criminal responsibility differed notoriously. He stated that it must be proved that at the time of committing the act the prisoner was suffering from a disease of the mind so that he did not know the nature of the crime which he was committing and that it was wrong. After the Ronald True case a commission was appointed to see if any change in the law was necessary and, if so, what change should be made, but no one was able to formulate more satisfactory tests than the M'Naghten rulings, and so no change was made. He noted that mental experts were not always in agreement over the state of the mind of a prisoner, whereas medical prison officers were of high standing in relation to insanity, and if necessary made a report on any case, and this was frequently followed by an inquiry; furthermore, all sentences of death were carefully inquired into before execution was carried out, and therefore he was of opinion that there should be no change in the present law.

Dr. WEATHERLY said that this was a subject which he had studied for over fifty years, and it was thirty-two years ago that he had, through the British Medical Association, brought the doctors and lawyers together to discuss this very subject. He stated that the present law was based on the M'Naghten ruling; this was panic legislation and therefore bad, as the judges who gave the answers to the questions had no knowledge of disease of the mind, and he was quite sure that justice could not be done if judges adhered rigidly to the M'Naghten ruling. Dr. Weatherly then related three cases which supported this contention. He thought that there was only one way in which the law could be altered; it was no good determining whether or not a man knew that he was doing wrong when he committed a crime, as most inmates of asylums knew the difference between right and wrong. He thought that there should be at least two degrees of murder, the jury to decide in which category any case should fall, and the judge to decide the penalty.

Mr. A. H. TREVANION said that he had listened with the greatest possible interest to what Dr. Weatherly had said, but he was strongly of the opinion that inasmuch as a prisoner was innocent unless proved guilty, so a prisoner was sane unless he was proved insane. As to the Ronald True case, when the appeal was taken to the House of Lords the defending counsel contended that if through disease of the mind a man committed a crime under an uncontrollable impulse he should be acquitted of responsibility, but the judges did not uphold this contention. As to dividing murder into two or more classes and leaving the decision to the jury, he thought that there would not be uniformity of classification, and on these grounds he would be opposed to it.

Dr. SIMMONS said that as a police surgeon he had to deal chiefly with minor offences; he was of the opinion that if a person committed a crime repeatedly in spite of being punished he must be suffering from some form of moral insanity even where there was no other evidence of it.

Mr. HAROLD SALT said that the safety of society was the first consideration of legislation; it was unsafe to argue from hard cases, and therefore he upheld the M'Naghten rules.

Dr. ASTEN thought it very curious that the M'Naghten rules should have remained unchanged for eighty years. If a man was found to be insane by a panel of mental experts he should not be held responsible for crime. He liked the French code, which laid down that there was no crime where there was insanity.

Mr. TILNEY BARTON, chairman of the Bournemouth Legal Society, said what a pleasure it had been for the lawyers to have had the opportunity of meeting the doctors and discuss such an interesting and important subject; he was quite sure that it had been a profitable as well as enjoyable meeting for all.

GLOUCESTERSHIRE BRANCH.

A MEETING of the Gloucestershire Branch was held at the Royal Infirmary, Gloucester, on December 9th, 1926, under the chairmanship of Dr. J. RUPERT COLLINS.

Dr. CAIRNS TERRY showed a man, aged 33, with a mediastinal tumour diagnosed by *x*-ray examination. The Wassermann reaction was negative and the blood picture and larynx were normal. The chief symptoms were attacks like asthma and shortness of breath. In the absence of definite signs reluctance was expressed to accept a diagnosis on *x*-ray films alone. Dr. Terry also showed microscope slides from a portion of a large tuberculous mass found at operation inside the abdomen of a child during a very acute illness.

The PRESIDENT mentioned two very dramatic cases of acute onset of abdominal tubercle in children. A child was brought to his out-patient department with a history of sudden illness with abdominal pain, the child having been quite well on the previous day. Death occurred ten minutes after the child was seen. The necropsy showed huge masses of tuberculous glands in the abdomen, some of which had suppurated. A few weeks later a small sister was brought to Dr. Collins, the mother reporting that only that morning vague abdominal symptoms had been noticed, and this time she was determined not to be too late. This child was at once

admitted to hospital, and was dead within twenty-four hours, the condition being similar to the first.

Mr. ARNOLD ALCOCK demonstrated three cases of knee-joint affections. A boy, aged 9, had bilateral synovitis, both knees distended with fluid. The Wassermann reaction was positive. A woman, aged 26, was admitted to hospital in considerable pain. She felt clicking in a knee-joint, and had previously had an operation, without benefit, for a displaced cartilage. After some hesitation the speaker had laid open the joint by a vertical incision through the patella and found rheumatoid arthritis with several loose bodies, which were removed. Both semilunar cartilages were still present. The third patient was a boy, aged 12, who had complained of pain in the inner side of the left knee-joint and showed slight flattening of the gluteal fold on the same side. He was admitted with a diagnosis of early hip-joint disease. Under rest all symptoms on the left side speedily disappeared, but pain began in the right knee. The cases were discussed by various members.

Mr. H. SMURTHWAITE showed a woman with complete adhesion of the soft palate to the pharynx; the condition was probably specific. He described the operative measures he proposed to undertake and promised to show the case again. Such a condition, in his experience, was very rare.

Dr. E. N. DAVEY gave a short address on pathology in relation to general practice, and mentioned certain elementary considerations which were nevertheless occasionally overlooked. Bacterial antisepsis must be equal to surgical antisepsis. Material should be collected at suitable times, as, for example, during pyrexia in the case of a blood culture, and not before the tenth day when a Widal test was to be performed. The amount of blood taken must also be adequate. There should be as little delay as possible in getting specimens to the laboratory. Dr. Davey strongly recommended taking blood direct from a vein with an ordinary hypodermic syringe. Disinfecting the skin with iodine was popular, but the dark colour might obscure the vein. A clear fluid, such as biniode, was recommended. He mentioned the normal urea content of blood—10 to 30 mg. per 100 c.cm. If this content exceeded 30 mg. then a pathological condition was present. In nephritis three-fourths of the kidney substance must be destroyed before any change in blood urea was shown. Stress was laid on the necessity for blood urea examinations before operations on the genito-urinary tract. This applied with especial force to prostatectomy. No such operation was ever undertaken now at the Royal Infirmary without this preliminary, and he was satisfied that results had improved in consequence. He dealt with the differential diagnosis in coma of unknown origin, including uraemia, diabetic coma, and hypoglycaemia, and described the method of plotting a curve for blood sugar tolerance. In his opinion blood cultures were becoming of more value. He showed a capsule which he recommended for conveying blood. It was sent out sterilized and containing 0.5 c.cm. sodium citrate solution. Blood to the extent of 5 c.cm to 10 c.cm. was withdrawn from a vein by a hypodermic needle, transferred to the capsule, and the end closed by sealing-wax. A positive blood culture nearly always foretold a fatal issue, especially in the case of the streptococcus. Dr. Davey also dealt with examinations of cerebro-spinal fluid and urine, pointing out with regard to the latter that for bacteriological purposes all specimens must be obtained by catheter. For tuberculosis a twenty-four-hour specimen was necessary, and there was no use going on with the examination unless pus was present.

The paper was of great interest and practical value, and Dr. Davey was heartily thanked. Twenty-three members subsequently dined together at the Spread Eagle Hotel.

LANCASHIRE AND CHESHIRE BRANCH: ROCHDALE DIVISION.

A MEETING of the Rochdale Division was held in the Lyceum, Rochdale, on December 15th, 1926, when Dr. KILROE was in the chair.

Dr. ANDERSON opened a discussion on the regulations on puerperal fever recently issued by the *Ministry of Health*. He considered that to carry out the regulations hospital accommodation, trained nurses, a specialist, and a bacteriologist would be required. A building at Marland Hospital quite separate from the other buildings could be converted into a suitable place with four cubicles for patients, accommodation for nurses, laboratory for diagnostic purposes, etc. A trained bacteriologist was necessary to examine the uterine secretions and to prepare a vaccine at once; stock vaccines were of no use. He did not consider that the treatment by drugs and antiseptics was of much use, and after the results of the treatment of scarlet fever by vaccines he hoped for excellent results from that method. After discussion approval of the Marland scheme was carried unanimously.

METROPOLITAN COUNTIES BRANCH: LEWISHAM DIVISION.

A MEETING of the Lewisham Division was held on December 21st, 1926, at the Town Hall, Catford, S.E.6, when Lieut.-Colonel CHARLES THOMSON took the chair. Dr. R. TRAVERS SMITH delivered an address on functional nervous disorders of the heart. He said that in the neuroses and psychoneuroses the patient presented somatic symptoms. Emotional distress was shown in the heart by subjective symptoms. Fainting which had a mental origin was a cerebral ischaemia due to vagus inhibition; nervousness was the main cause. Disordered action of the heart and tachycardia were neuroses. The cardiopath might become a neuropath and the neuropath might become a cardiopath. Disordered action of the heart might complicate organic disease, might aggravate heart lesions, and was sometimes misinterpreted as angina pectoris. Pain in and around the heart might be organic or neurotic. Organic pain was (*a*) more frequent in the elderly males, (*b*) substernal, (*c*) on exertion; and neurotic (*a*) more in youths a females, (*b*) depends more on emotion.

Drs. THOMSON, BUCHAN, HALLINAN, EVANS, GRAY, BAIN, BANNOUS CHARSLEY, and BEATTIE joined in the discussion, and a vote thanks was passed to the lecturer.

METROPOLITAN COUNTIES BRANCH: WILLESDEN DIVISION.

AT the meeting of the Willesden Division, held at St. Andrew Church Hall on December 15th, 1926, Dr. F. M. HARVEY, *M.C.*, re a paper on "The uses of ultra-violet rays by a general practitioner Dr. H. D. HALDIN-DAVIS described Dr. Harvey's effort as the mo luminous scientific paper he had ever heard, and gave h experience with the rays at the school clinics. Dr. W. W. STOCK also made an interesting contribution to the subject. On the moti of Dr. C. F. T. SCOTT, seconded by Dr. HEAL, a vote of thanks w accorded to the speakers. Dr. W. LOCK'S motion with regard minimum fees was carried, with the deletion of the words "f two days" after "with medicine."

A letter was read from the secretary of the Willesden Gener Hospital, pointing out that—(1) The Division's proposal of la December, that each practitioner should treat his patients in th wards of the hospital, was considered impracticable. (2) Arrang ments had been made for future appointments to the medical sta as already approved by the Division without prejudice to th whole question. (3) Any doctor not on the staff might send h patients to the doctor of his choice on the staff. (4) The chairma and honorary secretary were offered *ex officio* seats on the Hospit Council. It was decided to refer the letter to the Executive Cor mittee and to send a copy to each member.

NORTH OF ENGLAND BRANCH: DARLINGTON DIVISION.

A CLINICAL meeting of the Darlington Division was held Greenbank Hospital, Darlington, on December 16th, 1926, whe Dr. C. J. KIRK was in the chair and there was an exceptional good attendance, which included a large number of counti members and members of the neighbouring Divisions. Th speaker of the evening was Dr. FREDERICK PRICE, whose subje was "Recent important developments in cardiology." His lectu was an essentially practical one and the subject-matter pr foundly interesting; it was listened to with the closest attentio throughout. A hearty vote of thanks to Dr. Price for his addre was proposed by Dr. CHALMERS, seconded by Dr. SINCLAIR, an carried with acclamation.

NORTH OF ENGLAND BRANCH: HARTLEPOOLS DIVISION.

A MEETING of the Hartlepools Division was held on December 9t 1926, when the chairman, Dr. W. N. RISHWORTH, *M.C.*, presided

Dr. W. H. DICKINSON (Newcastle-on-Tyne) read a paper dealin with "The diseases of the chest as studied with the help of th *x* rays." After dealing with the methods of examination of th thorax, the lecturer demonstrated the normal appearances of th heart and lungs and the scheme of mapping out the lung fields fo radiographic purposes. This was followed by a brief description various pathological conditions of the lungs, heart, and great vesse with numerous lantern slides. After emphasizing the fact tha radiological examination was only to be regarded as one of th methods to be employed in investigating a chest case, Dr. Dickinso stated that in his opinion the use of the *x* rays was indispensable no other method giving such an accurate idea of the quantitative a well as the quantitative character of the lesions in most cases Finally, he pointed out that while the value of the method wa inestimable in assisting the physician to come to a positiv diagnosis, it was also of great service by enabling him to "rul out," definitely, certain pathological states in very many case presenting suggestive symptoms, but in which the physical sign were indefinite or negative.

OXFORD AND READING BRANCH: WINDSOR DIVISION.

A MEETING of the Windsor Division was held at the King Edward VI Hospital, Windsor, on December 17th, 1926.

Dr. REGINALD MILLER, honorary secretary of the British Medica Association Committee on Rheumatic Heart Disease in Children opened a discussion on "The national problem of rheumatic hear disease in children." He pointed out that the problem could b solved only by careful research into those conditions that surround the individual case. The disease was almost unknown in publi schools, but was rife in those children attending elementary school in London, but not among the very poor. Considerable discussion followed. Dr. HATHAWAY said that in twenty-three years he had had no case in Eton, in the Imperial Service College, or in private practice. Dr. SPROTT undertook to investigate the occurrence o the disease among elementary school children in Windsor to compare this with Eton's immunity. It was realized by all how much useful research might be carried through by such a body as a local Division of the British Medical Association.

SOUTH WALES AND MONMOUTHSHIRE BRANCH: CARDIFF DIVISION.

THE annual dinner and dance of the Cardiff Division was held on December 15th, 1926, when Dr. T. W. THOMAS (Caerphilly) presided. In proposing the toast of "The British Medical Association," Sir WILLIAM DIAMOND said that the medical pro fession was not troubled with ordinary industrial troubles, and it was never out of employment. Some of the characters in the medical profession he described as the salt of the earth, inasmuch as those members had cultivated that great quality which made

life really worth while; they had no mercenary ends. Cardiff would, he knew, be proud to receive the Association when it held its annual meeting there in 1928 under the presidency of Sir Ewen Maclean. The CHAIRMAN, in acknowledging the toast, said that the duties of medical men were onerous and demanded tact and skill. The profession did not seek riches; its first consideration was to do the best possible good for the people. Dr. W. E. THOMAS also responded; he said that there was at present no time to spare for differences among the members of the medical profession. Sir EWEN MACLEAN proposed the toast of "The Guests" and extended a hearty welcome to all present, and especially to the students from the Cardiff Medical School. The LORD MAYOR, in responding, said that his respect for the medical profession knew no bounds; Sir EDWARD SEAGER also acknowledged the toast.

SOUTH WALES AND MONMOUTHSHIRE BRANCH: SWANSEA DIVISION.

A MEETING of the Swansea Division took place on December 9th, 1926, at the General Hospital, Swansea, when Dr. H. R. FREDERICK, chairman of the Division, presided. Mr. HAROLD DAVIS, Ph.C., lecturer in pharmacy, Technical College, Swansea, gave a most able address on "Incompatibles." Several prominent pharmacists of the town and district attended the meeting and were warmly welcomed. A hearty vote of thanks to the lecturer was accorded at the conclusion of the meeting.

BOOKS ADDED TO THE LIBRARY.

THE following books were received by the Library of the British Medical Association during October and November, 1926:

Abt: Pediatrics. Volume 8 and General Index. 1926.
Anderson, W. H. P. and M.: Dawn and Gleam. 1926.
Backmeister-Rickmann: Die Röntgenbehandlung der Lungen und kehlkopf-Tuberkulose. 1924.
Beaumont and Dodds: Recent Advances in Medicine. Third edition. 1926.
Bensaude, R.: Traité d'Endoscopie. Second edition. 1925.
Blacker, C. P.: Birth Control and the State. 1926.
Borst, M.: F... ...6.
Bose, Y. M.: ... ...lth and Disease. 1925.
Boyd, M. F.: ... ...nd edition 1935.
Braun, M., u ... ... parasiten des Menschen. II Teil. 1926.
Brocq, P.: Les pancréatites aigües chirurgicales. 1926.
Buschke-Gumpert: Geschlechtskrankheiten bei kindern. 1926.
Carleton, H. M.: Histological Technique. 1926.
Chapin and Royster: Diseases of Children. Fifth edition. 1925.
Coca, A. F.: Essentials of Immunology. 1925.
Coleman, F.: Materia Medica for Dentists. Sixth edition. 1926.
Orile, G.: Bipolar Theory of Living Processes. 1926.
Darwin, L.: Eugenic Reform. 1926.
Dearle, N.: The Cost of Living. 1926.
Denker, A., u. Kahler, O.: Handbuch der Hals, Nasen, Ohrenheilkunde. VI. 1926.
Dental Board of United Kingdom. Four Lectures on General Anaesthesia. 1926.
Evans, C. L.: Recent Advances in Physiology. Second edition. 1926.
Fairbairn, J. S.: Obstetrics. 1926.
Fox, C.: Educational Psychology. 1925.
Gleason, E. B.: Diseases of the Nose, Throat, and Ear. Fifth edition. 1924.
Guy's Hospital Reports. Volume 76, 3. 1926.
Hall, Walter and Eliza: Institute for Research in Pathology. Collected papers. Volume 2. 1923-25.
Harms, O.: Die Entwicklungstadien der Lungentuberkulose. 1926.
Heatherley, F.: Modern Methods in the Diagnosis and Treatment of Heart Disease. Second edition. 1926.

ADMINISTRATION OF DENTAL BENEFIT.

ADDITIONAL details of the new arrangements for the administration of dental benefit which came into operation on October 1st, 1926, have now been published in a circular (A.S. 259) on behalf of the Ministry of Health and the Scottish Board of Health.

It is stated that the adoption of the new scale of charges by any society confers the right on the society to make use of the proposed service of regional dental officers, to adopt the model dental letter, and take advantage of the arrangements made by the Dental Benefit Joint Committee to deal with disputes. When dealing with the previous circular (SUPPLEMENT, October 9th, 1926, p. 161) we commented on the fact that dentists without a medical qualification are permitted by law to administer anaesthetics other than nitrous oxide for prolonged operations. It is now stated that a list of registered dentists who are eligible for anaesthetic fees has been approved by the Dental Benefit Joint Committee, and may be obtained by any society which has accepted the new agreed scale, though the list is not for publication in any way. It is added that, since any duly qualified medical practitioner is allowed to administer anaesthetics, the fee in his case is payable without reference to the list of anaesthetists.

A scheme for providing regional dental officers has now been approved by the Dental Benefit Joint Committee and the Consultative Council, and it will be brought into operation as soon as possible. The main features of this scheme are that seven full-time regional dental officers will be appointed in the first instance, of whom two will be stationed in London; one each in the areas centred upon Manchester, Birmingham, and Leeds; one in Cardiff; and one in Glasgow; arrangements being made for sessions at suitable places throughout these areas. The regional officers will examine estimates for dental treatment, and patients referred to them, including the consideration of quality, workmanship, or fitting of dentures. They will also make any inquiries necessary into the progress of dental treatment under the scheme. Their work will be supervised by the central departments, which will furnish reports from time to time to the Dental Benefit Joint Committee. It is further stated that a society providing dental benefit may not act arbitrarily in rejecting claims by its members, who have a right of appeal against its decision; the society may, however, discuss with the dentist the question of the necessity of any item included in a disputed estimate. Failing agreement, such a case may be referred by the society to the regional dental officer, whose opinion would ordinarily be accepted by both parties, though it will still be open for either the society or the dentist to appeal to the Dental Benefit Joint Committee. Pending the appointment of regional dental officers, any society in doubt about an estimate submitted by a dentist may refer the difficulty to a consulting dentist, or seek advice from one of the dental organizations.

Since there is a limit to the amount which any society providing dental benefit under the additional benefit scheme may spend in any year, the scheme provides for the possibility of transferring to the credit of the dental benefit account in any year a proportion of the amounts allocated to, but not required by, other treatment benefits. Moreover, such expenditure may be allowed to exceed the allocated amounts by not more than

10 per cent. in any year subject to recovery of the excess by a corresponding reduction in expenditure in the following year. In the event of difficulty with regard to such expenditure still persisting, suggestions are offered for its solution by a society obtaining sanction for amendment of its scheme or by other means.

LANCASHIRE INSURANCE COMMITTEE.

Laboratory Services.

THE following circular has been addressed to insurance practitioners on the medical list of the Insurance Committee for the county of Lancaster. As reproduced here the text has been slightly abridged.

The Lancashire Insurance Committee has formulated a scheme for assisting insurance practitioners in the scientific treatment of diseases which call for prompt pathological and bacteriological services, and for simplifying the administrative procedure where stock and autogenous vaccines are required.

An insured person is entitled, as part of medical benefit, to proper and sufficient drugs (including vaccines) requisite for the treatment of his case. This provision does not, however, extend to laboratory diagnostic services. If an autogenous vaccine is to be prepared, then, under the old procedure, the insurance practitioner selects the source of supply, obtains a collection and transmission outfit, and pays the laboratory authorities. He afterwards sends the receipted bill to the Insurance Committee, together with a *pro forma* prescription, when the cost is reimbursed to him. The large increase in the use of vaccines, and numerous inquiries received by the Committee from insurance practitioners, have emphasized the desirability for a simplification of procedure, and for relieving practitioners of much correspondence, payment of fees, and other clerical work.

The Insurance Committee has made arrangements with the Wigan Infirmary Pathological Department, presided over by Dr. W. E. Cooke, to supply stock and autogenous vaccines to the order of insurance practitioners, and to report upon material sent for examination. Insured persons, as such, are not entitled to laboratory diagnostic facilities, but it is understood that the Wigan Infirmary Board will be prepared to furnish free of cost diagnostic reports required by you for insured persons on your list. There will shortly be forwarded to you a free outfit for the collection and transmission of material, with postage prepaid, to the laboratory. Any part of the outfit used in connexion with the service will be immediately replaced. Should you require an autogenous vaccine, or report, you will send the necessary material, accompanied by brief details on the form provided, and, where an autogenous vaccine is to be prepared, a *pro forma* prescription, on the official form, giving the name of the patient, etc. Where a stock vaccine only is required all that need be sent to the Wigan Infirmary is a prescription on the official form. Payment will be made direct to the Infirmary Board by the Insurance Committee. For the purposes of this scheme, which comes into operation on January 1st, 1927, the laboratory is open day and night, and urgent examinations can be made at any time.

It should be clearly understood that the scheme as outlined above does not supersede existing arrangements for the supply of vaccines, but should be regarded as an alternative provision to be used at the option of the insurance practitioner. Practitioners are reminded that certain pathological and bacteriological services are provided free out of public funds through public health authorities, chiefly in connexion with tuberculosis, venereal diseases, diphtheria, and the typhoid group of fevers. Where practitioners have been notified of these services they should be used, and specimens sent to laboratories with which the local authority for the area has made arrangements, and the fee will be paid by the authority to the laboratory.

Correspondence.

A Public Medical Service.

SIR,—I have followed with interest the views of the sequence of contributors on the subject of panel patients and extra fees which have appeared in the SUPPLEMENT of late, and but for Dr. John Wilson's letter on December 11th, 1926 (p. 250), subscribing a "No! most emphatically" reply to the suggestion of a contributor that the Association should form a public medical service, I should not have been tempted—but for a special reason—to intervene in the discussion at this stage.

This suggestion is not new; towards the end of 1923, when practitioners were threatened with a reduction in the capitation fee, the Insurance Acts Committee strongly recommended those panel areas unprovided with an alternative service to take immediate steps to establish a public medical service, and I believe a number of Panel Committees complied. Nor is Dr. Wilson more fortunate in his equally emphatic assertion:

"I have no hesitation whatever in saying that the institution of such a thing in a practice introduces, in nine cases out of ten, the element of 'mere business' which is totally at variance with the true practice of medicine, and with its ideals as they ought to be and as some of us know them."

As the evidence of fact is much more convincing than a hypothetical deduction, the other side of the argument may be illustrated by reference to an historical example.

In 1895 the medical profession in Eastbourne, actuated by a determination to rescue four of their less favoured brethren from a pernicious alliance with the local branch of a touting "medical aid" company of lay shareholders, and conscious of their responsibility for the maintenance of professional integrity, organized their forces, by each member subscribing his declaration to wage unceasing aggressive warfare upon the enemy until the unholy thing was banished from their midst, and established their headquarters in the fastness of the newly founded "Eastbourne Provident Medical Association," a public medical service; with the result that, at the end of a fifteen months' strenuous campaign, the followers of the alien camp, numbering some hundreds, were sequestered within the precincts of the Provident Medical Association, and the alien enemy, being denuded of its "aids," was obliged to beat an ignominious retreat.

The doughty deeds of those pioneers in professional organization are enshrined in the third of a series of articles on "The Battle of the Clubs," written up at that time by the special commissioner of the *Lancet*, published in that journal, and reprinted in book form. The Eastbourne Provident Medical Association (for economy of space hereafter referred to as the "P.M.A."), with a membership wage limit, is self-supporting, and is entirely controlled and managed by the local profession. The membership is composed of women and children. In return for a weekly contribution of 3d. each, the members receive attendance and medicine. Fractures, dislocations, anaesthetics and major surgery, etc., are extras, chargeable on a fixed scale of fees. The services of an honorary consulting physician and surgeon are always available. Dental treatment, at reduced fees, is also provided. Right of "free choice" and liberty to "transfer" on the part of the member and medical officer have been in operation from the first. The staff of medical officers is open to any practitioner approved by the committee. Generally, the professional relationship between the members and medical staff is of the most cordial nature. During the thirty-one years there has not been a single complaint by a member against a medical officer, or vice versa, or dispute between members of the staff, brought to the notice of the executive of the P.M.A.

From the foregoing it will be seen that the P.M.A. very closely approximates to the ideal of what a public medical service should be, and through which the local profession might justly claim to have solved the problem of attendance on the "dependants of insured persons," in a way which secures each member's independence of State charity and guarantees the freedom of the practitioner from the injustices and inequities inherent in insurance practice.

While Dr. Wilson apparently bases his rooted objection to a public medical service on the ethical ground that the practice of medicine in England as compared with the same thing in Scotland is "simply a business, and a mercenary business at that," yet evidently he is enamoured with the method of remuneration under the National Health Insurance service, so long as each share is "sufficient for his daily bread and for moderate ease and comfort." The principle of *per capita* remuneration is common to the P.M.A. and N.H.I., except that in the former the definite contribution is paid to the practitioner, less 12 per cent. to cover the cost of working expenses; and I cannot conceive of any astute Scotsman regarding 3d. a week per member being the dominant "element of 'mere business'" in the one more than in the other.

Finally, if I may be permitted so to advise, I would recommend the insurance section of the profession to establish public medical services wherever possible, in order to forestall the contemplated inclusion of "dependants" in the national medical service suggested in the Report of the Royal Commission, and so keep the administration of this work in the hands of the profession as long as possible.—I am, etc.,

Eastbourne, Dec. 17th, 1926. WM. MUIR SMITH.

SIR,—I desire to thank "Another M.B." for his prompt and courteous reply.

While I repeat that £280 per annum, from the panel alone, is not to be scoffed at, I freely admit that it is not nearly as much as most of us would like in return for the work involved. I know all about the five years' study and the expense to the parents which is involved. What annoys me is the fact that many who have long ago paid off all such debts, and are now living in comparative affluence, are just the very men who grumble unceasingly at the remuneration they get from the panel.

I am well aware of all the panel shortcomings and deficiencies, but I do not see that it does any good for medical men to

grumble about it periodically in the correspondence columns of medical journals. I am not setting myself up as a champion of the panel system against the interests of my fellow practitioners; I am merely deprecating the attitude that certain men adopt in relation to it.

I can only repeat that, so far as I have had experience of various practices, both in Scotland and in England, the private practice was worth at least as much as the panel. I am quite prepared to admit, however, that this may be exceptional. —I am, etc.,

Glasgow, Jan. 3rd. JOHN WILSON, M.B., Ch.B.

SIR,—I think most panel doctors will thoroughly agree with what "Another M.B." writes in your issue of January 1st, p. 11. Dr. John Wilson's remarks (December 11th, 1926, p. 250) are mere platitudes, more fitting for a philanthropist, or for a doctor whose panel practice is merely a side line. The remuneration of panel doctors is not adequate for work done. But the worst feature of all is that frequently the rate of remuneration is not in strict accordance with the capitation basis (small as that is), but considerably below it. In other words, we do not even get what we agreed to accept. I can give a personal instance.

For the past quarter the number on my list was 28 more than for the previous quarter, yet instead of my cheque being greater it was less. Naturally I wrote for an explanation, but the only reason given was that the total acceptances for the county during the last quarter had increased to such an extent that the value of each unit had fallen by rather more than one halfpenny.

The Minister of Health is very particular about panel doctors fulfilling their obligations with regard to certification, keeping of records, and a hundred and one other matters. He ought to be just as particular about fulfilling his own obligations, at any rate in the matter of remuneration. If we panel doctors have agreed to accept service at the rate of 9s. 6d. per insured person on our lists then we ought to get it, and I think it is a matter for those who represent us to see that we do. —I am, etc.,

January 8th. L.R.C.P.

Naval and Military Appointments.

ROYAL NAVAL MEDICAL SERVICE.

Surgeon Commander E. C. Sawdy is placed on the Retired List with the rank of Surgeon Captain.

Surgeon Commanders C. T. Baxter and E. Heffernan to the *Victory* for R.N. Barracks; J. M. Gordon to the *Excellent*.

Surgeon Lieutenant Commander A. W. McRorie to the *Victory*, additional for R.N. Hospital, Haslar.

Surgeon Lieutenant L. P. Spero to the *Egmont*, additional for passage in the *Aphis* and the *Ladybird* as required, on joining, to take passage and do duty in *Cyclops* (appointment to *Victory* additional for R.N. Barracks cancelled); R. W. C. Ball to the *Ark Royal*; J. H. B. Crosbie to the *Bruce* (appointment to the *Centurion* cancelled); T. B. Lynagh, C. G. Rippin, and G. A. Miller to the *Bruce* additional; J. C. C. Boyle to the *Egmont* additional for duty in the *Wolverine* and the *Wanderer* as required, to take passage in the *Conquest*.

ROYAL NAVAL VOLUNTEER RESERVE.

D. R. Goodfellow has entered as Probationary Surgeon Lieutenant and attached to the Mersey Division.

E. C. W. Maxwell has entered as Probationary Surgeon Sublieutenant and attached to the London Division.

ROYAL ARMY MEDICAL CORPS.

Major-General O. L. Robinson, C.B., C.M.G., K.H.P., late R.A.M.C., having attained the age limit for retirement, retires on retired pay.

Lieut.-Colonel L. N. Lloyd, C.M.G., D.S.O., from R.A.M.C., to be Colonel to complete establishment.

Major A. De la Cour, O.B.E., M.C., to be Brevet Colonel.

Captain J. E. Foley retires, receiving a gratuity.

ROYAL AIR FORCE MEDICAL SERVICE.

Squadron Leader H. S. C. Starkey, O.B.E., to Headquarters, Irak.

Henry Penman is granted a short-service commission as a Flying Officer for three years on the Active List, with effect from and with seniority of October 8th, 1925, and is seconded for civil employment from October 8th, 1926, to October 7th, 1926, inclusive (substituted for notification in the *London Gazette* of October 26th, 1926).

M. D. Rawkins is granted a short-service commission as a Flying Officer for three years on the Active List.

INDIAN MEDICAL SERVICE.

The services of Major K. R. Batra are placed temporarily at the disposal of the Government of the Punjab.

The following promotion is made subject to His Majesty's approval: Major W. C. Gray to be Lieutenant-Colonel.

Colonel J. H. McDonald, K.H.P., and Lieut.-Colonel D. McCay, M.B., have retired.

REGULAR ARMY RESERVE OF OFFICERS.

ROYAL ARMY MEDICAL CORPS.

Captain W. S. Dawson resigns his commission and retains the rank of Captain.

TERRITORIAL ARMY.

ROYAL ARMY MEDICAL CORPS.

Major H. F. Wilkin, M.C., T.D., to be Brevet Lieutenant-Colonel.

Captain G. H. R. Gibson, D.S.O., to be Brevet Major.

TERRITORIAL ARMY RESERVE OF OFFICERS.

ROYAL ARMY MEDICAL CORPS.

Captain R. S. Morshead, M.C., from Active List, to be Captain.

COLONIAL MEDICAL SERVICES.

Dr. P. A. Clearkin appointed Director of Laboratory, Medical Department, Tanganyika. Dr. J. R. Tibbles appointed Assistant Medical Officer of Health and Assistant Port Health Officer, Mombasa, Kenya. Majors W. J. E. Bell, D.S.O., R. B. Price, D.S.O., and R. G. Martyn and Captain T. H. Twigg (all of the R.A.M.C.) appointed Medical Officer of Health, Senior Sanitary Officer, and Medical Officers respectively for Plague Duty in Nigeria. Dr. H. Gaston, M.C., has resigned his appointment of Medical Officer, Nigeria. Dr. G. R. C. Wilson transferred from Dodoma to Tanga, Tanganyika.

VACANCIES.

ADELAIDE UNIVERSITY.—Elder Professorship of Anatomy. Salary £1,100 per annum.

BIRMINGHAM: GENERAL HOSPITAL.—Medical Registrar and Resident Medical Officer. Salary £155 per annum.

HOOTLE BOROUGH HOSPITAL.—Honorary Radiologist.

BRADFORD ROYAL INFIRMARY.—House-Surgeon (male). Salary £150 per annum.

CAMBRIDGE: ADDENBROOKE'S HOSPITAL.—(1) Honorary Assistant Physician in charge of the Electrical and X-Ray Department. (2) Casualty Officer and Resident Anaesthetist (male, unmarried); salary at the rate of £130 per annum.

CARDIFF: UNIVERSITY COLLEGE OF SOUTH WALES AND MONMOUTHSHIRE.—Professor of Anatomy. Salary £1,000 per annum.

CITY OF LONDON HOSPITAL FOR DISEASES OF THE HEART AND LUNGS, Victoria Park, E.2.—House-Physician (male). Salary at the rate of £100 per annum.

EVELINA HOSPITAL FOR CHILDREN, Southwark, S.E.1.—House-Physician (male). Salary at the rate of £120 per annum.

HASTINGS: ROYAL EAST SUSSEX HOSPITAL.—Honorary Surgeon.

HOSPITAL FOR SICK CHILDREN, Great Ormond Street, W.C.1.—(1) Resident Medical Superintendent. (2) Physician to Out-patients. (3) Surgical Registrar. Salary for (1) and (3) £300 per annum.

LEAMINGTON SPA: WARNEFORD GENERAL HOSPITAL.—Resident House-Surgeon. Salary at the rate of £150 per annum.

LIVERPOOL MATERNITY HOSPITAL.—Two House-Surgeons. Salary at the rate of £90 per annum.

LONDON HOSPITAL, E.—Assistant Physician.

LONDON LOCK HOSPITAL, 91, Dean Street, Soho, W.1.—House-Surgeon at the Male Lock Hospital. Salary at the rate of £200 per annum.

MELBOURNE UNIVERSITY.—Director of Tubercular Research. Salary £1,000 per annum.

MILDMAY MISSION HOSPITAL, Austin Street, Bethnal Green, E.2.—Junior Resident Medical Officer (male). Salary £100 per annum.

NORTHAMPTON GENERAL HOSPITAL.—Honorary Assistant Surgeon.

PONTYPRIDD URBAN DISTRICT COUNCIL.—Woman Assistant Medical Officer. Salary £600 per annum.

ROYAL CHEST HOSPITAL, City Road, E.C.—Pathologist. Salary at the rate of £300 per annum.

ROYAL NATIONAL ORTHOPAEDIC HOSPITAL, 234, Great Portland Street, W.1.—(1) Honorary Surgeon. (2) Honorary Physician. (3) Honorary Dental Surgeon.

ROYAL WESTMINSTER OPHTHALMIC HOSPITAL, King William Street, Strand, W.C.2.—Six Refraction Assistants. Salary £100 per annum each.

RYDE: ROYAL ISLE OF WIGHT COUNTY HOSPITAL.—Resident House-Surgeon (unmarried). Salary at the rate of £180 per annum.

ST. THOMAS'S HOSPITAL, S.E.1.—Surgeon in charge of Out-patients.

SHEFFIELD: ROYAL INFIRMARY.—Ophthalmic House-Surgeon. Salary £80 per annum.

STAFFORDSHIRE GENERAL INFIRMARY, Stafford.—House-Surgeon (male). Salary at the rate of £200 per annum.

SOUTH LONDON HOSPITAL FOR WOMEN, Clapham Common, S.W.—(1) Clinical Assistants for Medical and Surgical Departments. (2) Clinical Assistant to the Ophthalmic Department.

VICTORIA HOSPITAL FOR CHILDREN, Tite Street, Chelsea, S.W.3.—(1) House-Physician. (2) House-Surgeon. Salary at the rate of £100 per annum each.

WARRINGTON INFIRMARY AND DISPENSARY.—Pathologist. Honorarium £50 per annum, *plus* charge per specimen.

WELSH BOARD OF HEALTH.—Medical Officer (woman). Remuneration £600 per annum, rising to £900, and thence to £1,000, with cost of living bonus in addition.

WORTHING HOSPITAL.—Honorary Radiographer.

YORK: COUNTY HOSPITAL.—House-Surgeon. Salary £150 per annum.

CERTIFYING FACTORY SURGEON.—The following vacant appointment is announced: Killin (Perthshire). Applications to the Chief Inspector of Factories, Home Office, Whitehall, S.W.1.

MEDICAL REFEREE UNDER THE WORKMEN'S COMPENSATION ACT, 1925, for Selkirk County. Applications to the Private Secretary, Scottish Office, Whitehall, S.W.1, by February 1st.

This list of vacancies is compiled from our advertisement columns, where full particulars will be found. To ensure notice in this column advertisements must be received not later than the first post on Tuesday morning.

APPOINTMENTS.

WESTMINSTER HOSPITAL.—*House-Physicians*: D. L. Delittle, M.B., B.S., M.R.C.S., L.R.C.P., and M. N. Oster, M.R.C.S., L.R.C.P. *House-Surgeons*: A. H. Levers, M.R.C.S., L.R.C.P., and C. M. Corbett, M.R.C.S., L.R.C.P. *Resident Obstetric Assistant*: M. P. McKelvey, M.R.C.S., L.R.C.P.

CERTIFYING FACTORY SURGEONS.—P. A. Ashcroft, M.R.C.S., L.R.C.P., for the Littleborough District, co. Lancaster; A. B. Pugh, M.R.C.S., L.R.C.P., for the Torrington District, co. Devon.

DIARY OF SOCIETIES AND LECTURES.

ROYAL SOCIETY OF MEDICINE.

Social Evening.—Mon., 8.30 p.m., Reception by the President and Lady Berry. 9.30 p.m., Address by Professor A. W. Sheen on Medicine in Ancient Greece (with illustrations).

Special General Meeting of Fellows.—Tues., 5.30 p.m., Alterations in By-laws; Ballot for Fellowship.

Section of Pathology.—Tues., 8.30 p.m., G. M. Findlay: Tar Tumours in Rats; J. A. Arkwright: The Values of Different Kinds of Antigens in T.A.B. Vaccines; P. Fildes: Tetanus; S. P. Bedson: Filtration of Herpes Virus through Collodion Membranes.

Section of History of Medicine.—Wed., 5 p.m., Dr. A. Currie: The Medical History of the First Three Wives of Henry VIII and their Offspring; Mr. W. R. Dawson: The History of Mummification.

Section of Surgery.—Wed., 8.30 p.m., Dr. J. M. T. Finney (Johns Hopkins Hospital): Pathology and Treatment of Gastric and Duodenal Ulcers.

Section of Dermatology.—Thurs., 4 p.m., Cases.

Section of Balneology and Climatology.—Fri., 4 p.m., Council Meeting. 4.30 p.m., Discussion: Climacteric Arthritis; to be opened by Dr. L. J. Llewellyn. Speakers: Drs. Barnes Burt, Warren Crowe, F. G. Thomson, R. G. Gordon, Bassett Jones, W. J. Midelton, Halls Daily, Vincent Coates, S. W. Patterson, and M. B. Ray.

Section of Obstetrics and Gynaecology.—Fri., 8 p.m., Joint Meeting of the Section with the Medico-Legal Society, with Lord Justice Atkin in the chair. Discussion: The Ethical, Legal, and Medical Aspects of Abortion. Speakers: Dr. J. S. Fairbairn, Lord Riddell, Dr. T. W. Eden, and Sir Travers Humphreys.

Section of Electro-Therapeutics.—Fri., 8.30 p.m., Discussion: Light Treatment in Surgical Tuberculosis; to be opened by Sir Henry Gauvain.

ROYAL SOCIETY OF TROPICAL MEDICINE AND HYGIENE, 11, Chandos Street, W.1.—Thurs., 7.45 p.m., Demonstration. 8.15 p.m., Professor J. W. W. Stephens, M.D., F.R.S. (Liverpool School of Tropical Medicine): The Haemoglobinurias.

CHELSEA CLINICAL SOCIETY, St. George's Hospital, S.W.—Tues., 8.30 p.m., Discussion: The Practical Results of Recent Researches in Infectious Diseases; to be opened by Dr. J. D. Rolleston, followed by Dr. R. A. O'Brien.

HUNTERIAN SOCIETY, Mansion House, E.C.—Mon., 9 p.m., Hunterian Lecture by Dr. J. M. T. Finney (Baltimore): The Influence of John Hunter on American Surgery.

MEDICO-LEGAL SOCIETY AND OBSTETRICAL SECTION OF THE ROYAL SOCIETY OF MEDICINE, 1, Wimpole Street, W.1.—Fri., 8 p.m., *Joint Discussion*: The Ethical, Legal, and Medical Aspects of Abortion. Speakers: Dr. J. S. Fairbairn, Lord Riddell, Dr. T. W. Eden, and Sir Travers Humphreys.

SOCIETY OF MEDICAL OFFICERS OF HEALTH, 1, Upper Montague Street, Russell Square, W.C.1.—Fri., 5 p.m., Discussion: The Education of the Public in regard to Modern Methods of Disease Prevention.

POST-GRADUATE COURSES AND LECTURES.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION, 1, Wimpole Street, W.1.—*Children's Clinic and the Royal Free Hospital*: Combined Course in Diseases of Children. Afternoons and some mornings. *Prince of Wales's General Hospital*, Tottenham, N.: Daily, 10.30 a.m. to 5.30 p.m. Intensive Course. *Royal Eye Hospital*, Southwark: Mon., Tues., Thurs., and Fri., Special Demonstrations at 3 p.m., free to members of the medical profession. *St. Mary's Hospital*, Paddington, W.: Wed., 2 p.m., Ward Round. Free to members of the medical profession. *Royal Northern Hospital*, Holloway Road, N.: Tues., Lecture: The Treatment of Varicose Veins by Injection. Free to members of the medical profession. *Bethlem Royal Hospital*, S.E.: Tues. and Sat., 11 a.m., Lecture Demonstrations on Psychoses. All information as to fees, etc., obtainable from the Secretary of the Fellowship of Medicine, 1, Wimpole Street, W.1.

CENTRAL LONDON THROAT, NOSE AND EAR HOSPITAL, Gray's Inn Road, W.C.1.—Fri., 4 p.m., Dysphagia.

HOSPITAL FOR SICK CHILDREN, Great Ormond Street, W.C.1.—Thurs., 4 p.m., Retropharyngeal Abscess.

LONDON SCHOOL OF DERMATOLOGY, St. John's Hospital, Leicester Square, W.C.2.—Tues., 5 p.m., Erythema Multiforme. Thurs., 5 p.m., Pathology Demonstration.

NORTH-EAST LONDON POST-GRADUATE COLLEGE, Prince of Wales's General Hospital, N.15.—Morning Demonstrations, 10.30 a.m. to 1 p.m.; Hospital Clinics, 2 to 4 p.m.; Clinical Lectures, 4.30 p.m. Mon., Prophylaxis of *Diphtheria and Scarlet Fever*. Tues., Treatment of Anxiety Neuroses. Wed., Modern Treatment of Toxaemias of Pregnancy. Thurs., Spectral "Heart Disease." Fri., Etiology and Treatment of Rheumatoid Arthritis.

POST-GRADUATE HOSTEL, Imperial Hotel, Russell Square, W.C.1.—Tues., 9 p.m., Surgery of Gastric and Duodenal Ulcer. Wed., 9 p.m., Acute Glaucoma. Thurs., 9 p.m., Early Recognition of Surgical Emergencies.

ROYAL NORTHERN HOSPITAL, Holloway Road, N.—Tues., 3.15 p.m., Treatment of Varicose Veins by Injection.

WEST LONDON HOSPITAL POST-GRADUATE COLLEGE, Hammersmith, W.6.—Mon., 10 a.m. to 1 p.m., Genito-Urinary Operations, Skin Department, Surgical Ward Visit, Demonstration of Fractures; 2 p.m., Surgical Wards, Gynaecological and Eye Departments. Tues., 10 a.m. to 1 p.m., Lecture on Clinical Methods, Demonstrations in Venereal Diseases and Chest Cases; 2 p.m., Medical Wards, Throat, Nose, and Ear Departments. Wed., 10 a.m. to 1 p.m., Children's Medical Out-patients, Medical Wards. Demonstration in Medical Pathology; 2 p.m., Surgical Wards, Eye Department. Thurs., 10 a.m. to 12 noon, Neurological Department; 2 p.m., Eye and Genito-Urinary Departments; 3 p.m., Gynaecological Wards. Fri., 10 a.m. to 1 p.m., Gynaecological Operations, Dental, Skin, and Electrical Departments; 2 p.m., Throat, Nose, and Ear Department. Sat., 10 a.m. to 1 p.m., Bacterial Therapy Department, Children's Medical Out-patients. Daily: Operations, Medical and Surgical Out-patients at 2 p.m.

GLASGOW POST-GRADUATE MEDICAL ASSOCIATION.—At Western Infirmary: Wed., 4.15 p.m., Medical Cases.

JAMES MACKENZIE INSTITUTE FOR CLINICAL RESEARCH, St. Andrews.—Tues., 4 p.m., So-called Acute Rheumatic Iritis.

Diary of the Association.

JANUARY.

14 Fri. London: Conference on Medical Defence, 2.30 p.m.
City Division: Clinical Meeting, Metropolitan Hospital, 4.15 p.m.

18 Tues. London: Organization Committee, 2.30 p.m.
Lewisham Division: Town Hall, Catford, S.E.6. Mr. C. A. Joll on Diseases of the Gall Bladder and Bile Ducts, 8.45 p.m.

19 Wed. London: Puerperal Morbidity and Mortality Subcommittee, 3 p.m.
Brighton Division: Royal Sussex County Hospital, 3.45 p.m.
Willesden Division: Willesden General Hospital, Harlesden Road, 9 p.m.

20 Thurs. Birmingham Branch: Birmingham Medical Institute. Dr. Douglas Stanley on Intrathoracic Tumours, 3.30 p.m.
North of England Branch: Scientific Meeting, Royal Victoria Infirmary, Newcastle-on-Tyne, 2.15 p.m.
North Lancashire and South Westmorland Branch: Kendal. Professor Fletcher Shaw on Lower Abdominal Pain in Women. Divisional Dinner, 7.30 p.m.

21 Fri. London: Maternity and Child Welfare Subcommittee, 2.30 p.m.
Leicester and Rutland Division: Medical Club, Bond Street, Leicester. B.M.A. Lecture by Mr. H. S. Souttar on the Clinical Aspects of Gastric and Duodenal Ulcers, 8.45 p.m.

25 Tues. London: Naval and Military Committee, 2.30 p.m.
Croydon Division: Croydon General Hospital. Sir Frank Colyer on Dental Sepsis, 8.30 p.m.

26 Wed. Cardiff Division: Engineers' Institute, Cardiff. B.M.A. Lecture by Professor W. E. Dixon on the Trend of Thought in Modern Therapy.
North Middlesex Division: Discussion on Insulin.
Oxford Division: Radcliffe Infirmary. Mr. H. Whitelocke on Impressions of American Surgery, 2.30 p.m.

27 Thurs. North Suffolk Division: Lowestoft Hospital. The Medical Secretary on the Essentials of a Medical Organization, 4 p.m.

28 Fri. London: Medical Students and Newly Qualified Subcommittee, 2.30 p.m.
Bishop Auckland Division: Dr. A. T. Paterson on Some Common Ailments of the Eye.

FEBRUARY.

9 Wed. London: Council, 10 a.m.

16 Wed. Sunderland Division: Royal Infirmary, Sunderland. Dr. A. Parkin on Pleural Effusion.

BIRTHS, MARRIAGES, AND DEATHS.

The charge for inserting announcement of Births, Marriages, and Deaths is 9s., which sum should be forwarded with the notice not later than the first post on Tuesday morning, in order to ensure insertion in the current issue.

BIRTH.

MCCREADIE.—On December 26th, 1926, at 2, Park Avenue, Nelson, Lancs, Muriel Harper, wife of A. J. McCreadie, *M.C.*, M.B., F.R.C.S.E., of a son.

MARRIAGES.

BLAIR—BROWN.—On January 8th, 1927, at St. James's Church, Gerrard's Cross, by the Rev. J. M. Glubb, M.A., assisted by the Rev. A. Laws, Leslie George Blair, son of Mr. and Mrs. Charles J. Blair of Birkenhead, to Olive Stewart Brown, daughter of Mr. and Mrs. Robert Brown of Rosegarth, Gerrard's Cross.

HOLDER—BERRY.—On January 12th, 1927, at the Church of St. Andrew's, Ashley Place, S.W.1, Sidney Ernest, son of the late Dr. William Holder and of Mrs. Holder of Holderness Road, Hull, to Violet Marjorie, only daughter of Mr. and Mrs. *Edmonds A. Berry of* 219, Ashley Gardens, S.W.1.

NORMAN—RANDLE.—On January 14th, at Edgbaston Parish Church, Birmingham, Rex Pridmore Norman, M.R.C.S., L.R.C.P., only son of Mrs. and the late Mr. John Norman of Sutton Coldfield, to Freda Henson Randle, M.B., Ch.B.Birm., daughter of Mr. and Mrs. F. Randle of "Clydesdale," Bristol Road, Birmingham.

DEATHS.

DISMORR.—On January 4th, 1927, at Purton, Wilts, Henry Bertram Dismorr, M.R.C.S.Eng., L.R.C.P.Lond., aged 49, formerly of Wroughton, near Swindon.

KELLY.—On December 3rd, 1926, in Tipperary, Dr. Dan Kelly, *M.C.*, late Captain R.A.M.C., late Heath Town, Wolverhampton, husband of Eileen Pomeroy Kelly, M.B., Ch.B.

MENZIES.—At a nursing home, Edinburgh, on December 22nd, 1926, James Morris Menzies, M.D., C.M., of Hawthornbank, Selkirk.

Printed and published by the British Medical Association, at their Office, Tavistock Square, in the Parish of St. Pancras, in the County of London.

CURRENT NOTES.

Some Work of the Week.

LAST week three of the Standing Committees held meetings—the Central Ethical, Hospitals, and Insurance Acts. The work of the Central Ethical Committee is largely of a nature which cannot be reported, because the Committee is dealing largely with disputes and complaints, and the success of its action depends much on the fact that its proceedings are strictly confidential. It had a report that a binding resolution as regards the scale of minimum commencing salaries for public health medical officers had now been adopted by 16 Branches out of 26, 2 Division-Branches out of 3, and 69 Divisions out of 152; the Medical Secretary was instructed to do all he could to stimulate the units which had not taken action. The Committee dealt with ethical rules which had been submitted by the Federal Council of the Medical Association of South Africa (British Medical Association).

The Hospitals Committee had before it a report concerning the dispute at the Hertford British Hospital, Paris, and appointed a subcommittee to deal with questions arising out of the matter. It directed the preparation of a memorandum dealing with the fundamental principles of the policy of the Association as to contributory schemes, with a view to this being circulated to the medical staffs of voluntary hospitals and some cottage hospitals. The Committee recommended to the Council that counsel's opinion should be obtained on the legal position of hospitals in regard to the recovery of money in respect of the treatment of patients, and advised upon various hospital questions submitted to it by individuals and hospital staffs.

The Insurance Acts Committee considered a report of a subcommittee on the question of possible alteration of the present unrestricted free choice of doctor in connexion with the recent heavy increase in sickness benefit claims. It agreed that so far as the professional aspect of the matter is concerned the present unfettered free choice of doctor by patient is the ideal principle in any scheme of national health insurance, and that it would not be advisable to return to the old arrangement under which insured persons could only change their doctor at definite dates, but that there are certain conditions under any national health insurance scheme as compared with private medical practice which affect the position in several ways, and may necessitate some modification of the present procedure as regards change of doctor. The Committee decided to place these points before the Ministry. The Statistics Subcommittee, appointed some time ago to deal with a motion of the Panel Conference, presented a report, and the Committee agreed that the statistical work already being done in the office sufficed for present needs, but that if the occasion arose additional staff would be appointed. The Committee had before it also a report from the deputation which waited on the Ministry of Health on November 30th last, dealing with disciplinary procedure and other points arising out of the Panel Conference; a subcommittee was appointed to consider and report on the whole of the disciplinary procedure, with recommendations as to whether, and if so in what manner, such machinery could be improved so as to obviate the many complaints now made by practitioners; it is intended that the proposals shall be discussed between the Insurance Acts Committee and the Ministry. A resolution of the Birmingham Panel Committee protesting against the proposal to abolish Insurance Committees and transfer their powers to local authorities was also considered, and it was agreed that a memorandum should be drawn up restating the policy of the Association in regard to the unification of health authorities, with particular reference to the position of Insurance Committees. Advice was given also to many Panel Committees on questions raised by them. At the close of this meeting of the Insurance Acts Committee the Trustees of the National Insurance Defence Trust met, dealt with current business, and gave instructions that as soon as possible the assessment of each Committee in raising the £250,000 which is to be aimed at should be sent to Panel Committees.

On January 14th a few representatives of the Association met representatives of the Medical Defence Union and of the London and Counties Medical Protection Society, and discussed with them in a friendly and informal way certain points arising in correspondence in the JOURNAL last year, which showed that some practitioners were not satisfied with the extent of the protection afforded to them under their insurance with these societies. The representatives of the societies promised to take into early consideration the points raised.

The Deputy Medical Secretary by invitation attended the inaugural meeting of the new British Pathologists' Association on January 7th, and advised those present as to the best ways of organizing themselves, with particular reference to liaison with the British Medical Association. On January 12th the Medical Secretary visited the Tower Hamlets Division, and met a few of its active members, though the projected Division meeting fell through.

Meetings of Branches and Divisions.

AUSTRALIA: VICTORIAN BRANCH.

The Year's Work.

THE annual report of the Victorian Branch for the year ending December 1st, 1926, illustrates various ways in which steady progress has been made. The number of members has increased from 1,256 in the preceding year to 1,311. The Council has dealt with certain ethical matters, and it has been decided that all applicants for membership of the Branch shall receive before election a copy of the "Ethical Principles," and that these Principles shall be printed also on the back of the application form for membership. The attention of the Chief Secretary of the State was drawn to the fact that there was no authority with disciplinary powers over medical practitioners such as existed in other States and in Great Britain, except in cases of conviction for felony. On several occasions where the wireless broadcasting of medical subjects had been proposed the approval of the Council had been sought and its opinion respected. The Council had arranged for a lecturer to broadcast matters relating to first aid, and resolved that it was desirable that all public pronouncements of this kind on medical subjects should be made anonymously by members approved by the Council. During the year successful subdivisional meetings had been held in different towns, the programme in each case including a clinical meeting at a hospital on the Saturday afternoon, a dinner and the reading of papers in the evening, with an excursion on the following day. The meetings had been well attended, and the programmes were of great scientific value. The Medical Agency continues to prosper, though not yet receiving the full support that is desirable. Early in 1926 an addition was made to the title of the Melbourne Post-Graduate Committee to indicate the fact that this committee was founded by the Victorian Branch in February, 1920. In addition to a fortnightly residential post-graduate course, sixteen weekly lectures were given, with an average attendance of about sixty. Lecturers had also visited country districts when invited. Professor Wood Jones gave a series of four lectures on some wider problems of the central nervous system, which proved very popular. A subcommittee has been appointed by the Council to deal with cancer propaganda. The Branch welcomed recent graduates at an evening entertainment in June, when addresses were given by members of the Council, and a good musical programme was arranged. Ten monthly meetings of the Victorian Branch, with seven clinical meetings, and eight special meetings, were held during the year. The lecturers included Dr. Malcolm MacEachern of the American College of Surgeons, Sir James Barrett, Dr. Colin Mackenzie, and Dr. Marshall Allan. The library was more freely used than in previous years, and over one hundred books were added to it.

SUSSEX BRANCH: HASTINGS DIVISION.

AT a meeting of the Hastings Division held in the Queen's Hotel on January 4th, Dr. G. T. HEBERT, physician in charge of the tuberculosis department, St. Thomas's Hospital, read a paper on "The [illegible] signs." The lecture was illustrated by a [illegible] iagrams. Dr. Hebert gave a very clear [illegible] of the commoner physical signs found [illegible] common pitfalls were discussed and useful practical hints were given as to how they were to be avoided. The lecture was listened to with great attention.

Association Notices.

BRANCH AND DIVISION MEETINGS TO BE HELD.

BIRMINGHAM BRANCH: COVENTRY DIVISION.—At the meeting of the Coventry Division, arranged for Tuesday, February 1st, Mr. Baron T. Rose will read a paper on "Surgical matters of interest to general practitioners."

BIRMINGHAM BRANCH: NUNEATON AND TAMWORTH DIVISION.—A meeting of the Nuneaton and Tamworth Division will be held at the Red Lion Hotel, Atherstone, on Wednesday, February 2nd, at 3.30 p.m. The meeting will be mainly a clinical and pathological one, and members are invited to show patients or specimens. Those who wish to do so are asked to communicate previously with Dr. Pracy, Colville House, Atherstone (telephone number, Atherstone 23), who is arranging the meeting. Patients should be in attendance from 3.30 to 3.45 p.m.

DORSET AND WEST HANTS BRANCH: WEST DORSET DIVISION.—A meeting of the West Dorset Division will be held on Thursday, January 27th, at 8 p.m., at the County Hospital, Dorchester. Cases will be shown by the medical and surgical staff; by Dr. G. G. Morrice (two cases of cutaneous eruption); and by Dr. F. L. Nash-Wortham (specimen of vesical calculi removed from a boy aged 3½, also specimens of tuberculous kidneys). Dr. E. W. Smerdon will read a paper on his experiences at a post-graduate course.

LANCASHIRE AND CHESHIRE BRANCH: MID-CHESHIRE DIVISION.—The annual general meeting of the Mid-Cheshire Division will be held on Sunday, January 23rd, at 4 p.m. in the Board Room of the Altrincham General Hospital. Tea will be served at 3.45 p.m. Agenda: Report of the Executive Committee and financial statement; election of officers for 1927; recognition of Dr. Garstang's services; any other business. The attendance of members at this meeting is earnestly requested.

METROPOLITAN COUNTIES BRANCH: HAMPSTEAD DIVISION.—At the meeting of the Hampstead Division to be held on Thursday, February 10th, at 8.30 p.m., Mr. W. H. Trethowan, orthopaedic surgeon to Guy's Hospital, will read a paper on "Pain in the back."

METROPOLITAN COUNTIES BRANCH: LEWISHAM DIVISION.—At a meeting of the Lewisham Division to be held at the Town Hall, Catford, S.E.6, on Tuesday, February 15th, at 8.15 p.m., Dr. Alfred Cox, the Medical Secretary, will deliver an address on "The medical profession in South Africa."

METROPOLITAN COUNTIES BRANCH: NORTH MIDDLESEX DIVISION.—At the meeting of the North Middlesex Division to be held on Wednesday, January 26th, a discussion on insulin will be opened by Dr. G. Grant Macdonald.

METROPOLITAN COUNTIES BRANCH: ST. PANCRAS DIVISION.—A meeting of the St. Pancras Division will be held at the British Medical Association House, Tavistock Square, W.C.1, on Tuesday, February 8th, at 9 p.m., when Dr. Webb-Johnson will speak on "Obesity: its causes and modern treatment."

METROPOLITAN COUNTIES BRANCH: SOUTH MIDDLESEX DIVISION.—A meeting of the South Middlesex Division will be held at St. John's Hospital, Twickenham, on February 9th.—8.15 p.m., general business; 8.30 p.m., paper by Dr. A. B. Porteous, assistant clinical bacteriologist, St. Mary's Hospital, on "Transfusion, immuno-transfusion of blood."

MIDLAND BRANCH: CHESTERFIELD DIVISION.—The following programme has been arranged for the Chesterfield Division:—Friday, January 28th: Address on "Passive immunity," by Professor J. S. C. Douglas (Sheffield). Friday, February 25th: Address on "Gynaecological diagnosis," by Professor Miles Phillips (Sheffield). Wednesday, March 9th: Annual dinner, to be attended by Dr. Alfred Cox, Medical Secretary, British Medical Association. Friday, March 25th: Address on "Hysterectomies," by Mr. A. M. Webber (Nottingham). Wednesday, April 13th: Clinical and pathological demonstrations, 3 p.m. Friday, April 29th: Address on "The diagnosis and treatment of pneumococcal infections in childhood," by Dr. L. G. Parsons (Birmingham). Wednesday, May 11th, British Medical Association Lecture on "Chronic abdominal enlargement in children," by Dr. Reginald Miller (London), 3 p.m. Friday, May 27th: Address on "Injuries met with in coal-mining and their treatment by the general practitioner," by Professor A. M. Connell (Sheffield). All the fixtures for Friday evenings will take place at 8.15 p.m. at the Maternity Hospital, Chesterfield. Tea and coffee at 8. The Wednesday afternoon meetings will take place at the Royal Hospital, Chesterfield.

NORTH OF ENGLAND BRANCH: BISHOP AUCKLAND DIVISION.—At the meeting of the Bishop Auckland Division arranged for Friday, January 28th, Dr. A. T. Paterson (Durham) will lecture on "Some common ailments of the eye."

NORTH OF ENGLAND BRANCH: SUNDERLAND DIVISION.—The annual meeting of the Sunderland Division will be held at the Royal Infirmary, Sunderland, on Tuesday, January 25th, at 8.15 p.m. Agenda: Election of officers, committees, etc.; reception of reports of elections; annual report; report of Executive Committee. A dance will be held about February or March in conjunction, it is hoped, with the West End and Bishopwearmouth East Medical Societies. Further information may be obtained from the convener of the Dance Subcommittee, Dr. N. F. Rowstron.

OXFORD AND READING BRANCH: OXFORD DIVISION.—The first meeting of the year of the Oxford Division will be held at the Radcliffe Infirmary on Wednesday, January 26th, at 2.45 p.m. Agenda: Dr. J. C. R. Freeborn will demonstrate two instruments he has found of value in practice—(1) a uterine dilator, and (2) an abdominal rubber. Mr. E. C. Bevers will show an unusual foreign body from a motor-cycle accident. Mr. Hugh Whitelocke will give his impressions of American surgery.

SOUTH MIDLAND BRANCH: BEDFORDSHIRE DIVISION.—A general meeting of the Bedfordshire Division will be held at the Bedford County Hospital on Tuesday, January 25th, at 3 p.m. Agenda: Communication from Bedfordshire Branch of British Empire Cancer Campaign Fund; medical charities; discuss proceedings of Council (see SUPPLEMENT, BRITISH MEDICAL JOURNAL for January 1st, 1927); Mr. W. G. Nash will read notes on "Some interesting abdominal cases." Tea will be provided. Twenty-two members have contributed £4 4s. towards the Badge Fund, leaving the honorary secretary £3 5s. out of pocket; he will be glad to receive further subscriptions.

SOUTH WALES AND MONMOUTHSHIRE BRANCH.—A clinical meeting of the South Wales and Monmouthshire Branch will be held at the Hotel Metropole, Swansea, on Thursday, January 27th, at 3.30 p.m. Agenda: (1) "Stillbirths and early infant deaths," by Dr. Thomas Evans (medical officer of health, Swansea); (2) "Treatment of eclampsia in general practice," by Dr. Cellan Jones; (3) a case of partial gastrectomy (specimen) by Mr. Howell W. Gabe; (4) demonstration by Dr. A. F. S. Sladden; (5) demonstration of slit-lamp by Mr. H. E. Quick; (6) skiagrams by Dr. Iwan Davies.

SOUTH WALES AND MONMOUTHSHIRE BRANCH: CARDIFF DIVISION.—At the meeting of the Cardiff Division to be held at the Engineers' Institute, Cardiff, on Wednesday afternoon, January 26th, Professor W. E. Dixon, M.D., F.R.S., will give a British Medical Association Lecture on "The trend of thought in modern therapy."

SUFFOLK BRANCH: NORTH SUFFOLK DIVISION.—A meeting of the North Suffolk Division will be held at the Lowestoft Hospital on Thursday, January 27th, at 4 p.m. Dr. Alfred Cox (Medical Secretary of the Association) will give an address on "The essentials of a medical organization." Non-members are cordially invited.

SUFFOLK BRANCH: SOUTH SUFFOLK DIVISION.—The annual meeting of the South Suffolk Division will be held at the Crown and Anchor Hotel, Ipswich, on Friday, January 28th, at 3.30 p.m. Agenda: Business arising out of minutes; representative and Flag Fund; Charities Fund; annual report and balance sheet; election of officers for 1927.

SURREY BRANCH: CROYDON DIVISION.—A meeting of the Croydon Division will be held at the Croydon General Hospital on Tuesday, January 25th, at 8.30 p.m. Sir Frank Colyer will give an address on "Dental sepsis in relation to other pathological conditions."

SURREY BRANCH: GUILDFORD DIVISION.—A meeting of the Guildford Division will be held at the Royal Surrey County Hospital, Guildford, on Thursday, February 3rd, at 4 p.m. Mr. T. P. Dunhill will discuss the diagnosis of gall stones. Tea served at 3.45 p.m.

SURREY BRANCH: REIGATE DIVISION.—At the meeting of the Reigate Division to be held at the East Surrey Hospital, Reigate, on Tuesday, February 8th, at 8.45 p.m., Sir William Willcox, C.B., C.M.G., will speak on "The etiology and treatment of fibrositis (chronic rheumatism)."

SUSSEX BRANCH: HASTINGS DIVISION.—The next meeting of the Hastings Division will be held on Tuesday, February 1st, at 8.15 p.m., at the Queen's Hotel, Hastings. Dr. F. C. Martley will read a paper on "The benefits of co-operation in insurance for the medical profession, and what has been done to supply it." Coffee will be provided at 8.15 p.m.

WILTSHIRE BRANCH: SALISBURY DIVISION.—A meeting of the Salisbury Division will be held in the Museum Lecture Theatre, St. Ann Street, Salisbury, on Wednesday, January 26th, at 8.15 p.m., when Dr. E. P. Poulton, of Guy's Hospital, will lecture on "The therapeutic value of endocrine gland products." It is hoped that all members of the Division will make an effort to be present. Dinner will be provided at the White Hart Hotel at 7.15 p.m. for all members who wish it. Members intending to be present at the dinner are requested to notify the secretary not later than Monday next.

National Insurance.

SECOND VALUATIONS OF APPROVED SOCIETIES.

THE report by the Government Actuary on the second valuations of the assets and liabilities of approved societies has just been issued.[1] It provides a general survey of the working of the scheme of National Health Insurance from December 31st, 1918, the date of the first valuations of approved societies, up to the second valuations, which were effected as a matter of convenience and economy in two groups, valued respectively as at December 31st, 1922 and 1923. The following summary has been issued by the Ministry of Health.

The report shows that at the valuation date the total membership of approved societies exceeded 15 millions, of which approximately two-thirds consisted of men. The general result of the valuation is to disclose a very strong financial position, the total surpluses exceeding £42,000,000. Out of 8,135 societies and branches separately valued, 7,998 showed surpluses, and the remainder relatively small deficiencies, amounting to less than £100,000 in the aggregate. Of the above surpluses, it has been found possible to certify that a sum of £27,000,000 is available for distribution as additional benefits in the ensuing quinquennium, the number of members entitled to participate being nearly 14¾ millions, or 97 per cent. of the total number insured.

The report supplies an analysis of the various items of profit and loss which have combined to produce the total surplus of £42,000,000, of which £26,000,000 was earned during the period under review, the remainder having been carried forward from the preceding valuation. Prominent among the factors which have contributed to the growth of surplus has been the favourable sickness experience during the intervaluation period, especially as regards men. The claims of women, though less than the sum provided for, showed a continuous increase, particularly in the case of prolonged sickness. Another factor of great importance was the high rate of interest which societies have secured on their investments. On the other hand, the prolonged industrial depression has had its inevitable effect in the shortage of contribution income. These and other features are examined in the report, and various analyses of the experience according to type of society, occupational conditions, etc., are provided, and the position of societies having men and women in common insurance is contrasted with that of societies limited to men or women members. A section is devoted to the claims for maternity benefit and the effect of the decline in the birth rate.

[1] Cmd. 2785. H.M. Stationery Office. 2s. 6d.

The valuations were made on the same basis as was prescribed when the scheme was initiated, but references are made to the effect of the recent changes in the financial basis, which came into operation after the close of the intervaluation period, the chief of which is to supplement the provision made for the sickness claims of women, the new standard being about 60 per cent. above that adopted for men, which in view of the favourable experience in the past has been reduced by one-ninth. Further, the revised basis will have due regard to changes in the earning power of money, the improved vitality in the industrial population, and the reduction in the birth rate.

It is pointed out in the report that the level of surpluses brought out on the present occasion is markedly higher than that disclosed in 1918, and that of the surplus accrued during the first eleven years of the existence of the scheme, amounting to over £50,000,000, a substantial part is the direct or indirect consequence of the war. Of this sum a considerable proportion has already been applied in the provision of additional benefits until the next valuations, and the remainder, which is carried forward, should, in the opinion of the Government Actuary, "greatly assist in the continuance of additional benefits, of which there is reasonable expectation, provided that a high standard of administration by the approved societies is maintained, that the full co-operation of the medical profession in regard to the certification of claims is ensured, and that such unfavourable visitations as that which has been encountered in the present year (1926) prove to be transient. It should be understood that after giving effect to the recent changes by which the State grant has been reduced and the charges upon the funds of the societies in regard to medical benefit have been increased, the financial basis of the scheme remains one of undoubted strength."

Naval and Military Appointments.

ROYAL NAVAL MEDICAL SERVICE.

Surgeon Lieutenant Commander E. B. Kelley to the *Pembroke* for R.N. Hospital, Chatham.

Surgeon Lieutenant R. W. Mussen to the *Ganges* for R.N. Sick Quarters, Shotley.

Messrs. T. Prentice, P. H. Denny, C. R. Boland, and G. Rorison have entered as Surgeon Lieutenants and appointed to R.N. Hospital, Haslar, for course of instruction.

ROYAL NAVAL VOLUNTEER RESERVE.

Surgeon Sublieutenant H. Willoughby to the *Marlborough* for twenty-five days' training.

ROYAL ARMY MEDICAL CORPS.

The following Captains to be Majors: N. Cameron, with precedence next below R. G. Martyn, September 19th, 1926 (substituted for notification in the *London Gazette*, September 24th, 1926); W. S. Evans, with precedence next below M. Morris.

ROYAL AIR FORCE MEDICAL SERVICE.

Flight Lieutenant A. A. Townsend is granted a permanent commission in this rank.

The following Flying Officers are promoted to the rank of Flight Lieutenant: J. MacC. Kilpatrick and F. L. White.

Flying Officers M. D. Rawkins to No. 2 Flying Training School, Digby; J. E. Foran and M. O'Regan to Research Laboratory and Medical Officers' School of Instruction on appointment to short-service commissions.

INDIAN MEDICAL SERVICE.

Captains to be Majors: B. Z. Shah, A. J. D'Souza, M.C., R. H. Malone, V. N. Agate, J. P. Canteenwalla, L. S. Modi, S. N. Mukerji, B. C. Ashton, M. S. Joshi, K. B. Bharucha, E. R. Daboo, M.C., H. S. Anand, B. G. Mallya, and B. H. Kamakaka, M.C.

VACANCIES.

ADELAIDE UNIVERSITY.—Elder Professorship of Anatomy. Salary £1,100 per annum.

BANCHORY SANATORIUM.—Medical Superintendent.

BIRKENHEAD BOROUGH HOSPITAL.—(1) Honorary Surgeon. (2) Honorary Physician.

BIRMINGHAM: GENERAL HOSPITAL.—Medical Registrar and Resident Medical Officer. Salary £155 per annum.

BRISTOL MENTAL HOSPITAL.—Second Assistant Medical Officer (unmarried). Salary £400 per annum, rising to £450.

CAMBRIDGE: ADDENBROOKE'S HOSPITAL.—(1) Honorary Assistant Physician in charge of the Electrical and X-Ray Department. (2) Honorary Assistant Surgeon in charge of the Ear, Nose, and Throat Department. (3) Casualty Officer and Resident Anaesthetist (male, unmarried); salary at the rate of £130 per annum.

CENTRAL LONDON THROAT, NOSE AND EAR HOSPITAL, Gray's Inn Road, W.C.1.—Resident House-Surgeon (male). Remuneration £75 per annum.

CROYDON GENERAL HOSPITAL.—Junior Physician.

ELING BOROUGH.—Woman Assistant Medical Officer of Health. Salary £600 per annum.

EDINBURGH: ELSIE INGLIS MEMORIAL MATERNITY HOSPITAL, Abbeyhill.—(1) Senior House-Surgeon. (2) Two Junior House-Surgeons.

EDINBURGH HOSPITAL FOR WOMEN AND CHILDREN.—(1) Senior House-Surgeon. (2) Two Junior House-Surgeons. Salary at the rate of £25 per annum for (2).

EDINBURGH: ROYAL EDINBURGH HOSPITAL FOR SICK CHILDREN.—Five Honorary Resident Medical Officers.

ITALIAN HOSPITAL, Queen Square, W.C.1.—Honorary Assistant Anaesthetist.

LIVERPOOL CANCER AND SKIN HOSPITAL.—Honorary Biochemist.

LONDON HOMOEOPATHIC HOSPITAL, Great Ormond Street, W.C.1.—Assistant Physician.

LONDON HOSPITAL, E.—Assistant Physician.

LONDON JEWISH HOSPITAL, Stepney Green, E.1.—Assistant Surgeon in the Ear, Nose, and Throat Department.

LONDON LOCK HOSPITAL, 91, Dean Street, Soho, W.1.—House-Surgeon at the Male Lock Hospital. Salary at the rate of £200 per annum.

MACCLESFIELD GENERAL INFIRMARY.—Second House-Surgeon. Salary £150 per annum.

MANCHESTER: CHRISTIE HOSPITAL.—Anaesthetist. Honorarium £25 per annum for one morning a week, or £50 for two mornings.

NATIONAL HOSPITAL, Queen Square, W.C.1.—Registrar. Salary £200 per annum.

NORTHAMPTON GENERAL HOSPITAL.—(1) Honorary Assistant Surgeon. (2) Two House-Surgeons; salary £150 per annum each.

QUEEN'S HOSPITAL FOR CHILDREN, Hackney Road, E.2.—Casualty Officer. Salary at the rate of £100 per annum.

ROYAL CHEST HOSPITAL, City Road, E.C.—Pathologist. Salary at the rate of £300 per annum.

ROYAL NATIONAL ORTHOPAEDIC HOSPITAL, 234, Great Portland Street, W.1.—(1) Honorary Surgeon. (2) Honorary Physician. (3) Honorary Dental Surgeon.

ROYAL WATERLOO HOSPITAL FOR CHILDREN AND WOMEN, Waterloo Road, S.E.1.—Honorary Medical Registrar.

ST. THOMAS'S HOSPITAL, S.E.1.—Surgeon in charge of Out-patients.

SHROPSHIRE ORTHOPAEDIC HOSPITAL, Oswestry.—Junior House-Surgeon. Salary £150 to £250 per annum, according to experience.

UNIVERSITY COLLEGE HOSPITAL, Gower Street, W.C.1.—(1) Associate Physician. (2) Associate Surgeon.

UNIVERSITY COLLEGE HOSPITAL MEDICAL SCHOOL, W.C.1.—Demonstrator in Bacteriology (part-time). Salary £250 per annum.

WELSH BOARD OF HEALTH.—Medical Officer (woman). Remuneration £600 per annum, rising to £900, and thence to £1,000, with cost of living bonus in addition.

CERTIFYING FACTORY SURGEONS.—The following vacant appointments are announced: Cricklade ... rns (Renfrewshire), St. Columb ... applications to the Chief Inspector ..., S.W.1.

MEDICAL REFEREE UNDER THE WORKMEN'S COMPENSATION ACT, 1925, for the West Bromwich County Court District (Circuit No. 25). Applications to the Private Secretary, Home Office, Whitehall, S.W.1, by February 4th.

This list of vacancies is compiled from our advertisement columns, where full particulars will be found. To ensure notice in this column advertisements must be received not later than the first post on Tuesday morning.

APPOINTMENTS.

FRETTS, H. E. King, F.R.C.S.Edin., Honorary Assistant Surgeon to the Weymouth and District Hospital.

ST. MARY'S HOSPITAL, Paddington, W.2.—*Physician for Mental Diseases:* G. W. B. James, M.D., D.P.M., *M.C. Medical Registrar:* W. S. C. Copeman, M.A., M.B., B.Ch.

DIARY OF SOCIETIES AND LECTURES.

ROYAL SOCIETY OF MEDICINE.

Section of Odontology.—Mon., 8 p.m., Dr. J. H. Maclean: The Bacteriology of Dental Caries; Professor H. P. Pickerill (New Zealand): Non-eruption of Teeth.

Sections of Medicine, Surgery, and Laryngology.—Tues., 5 p.m., Special Discussion: Treatment of Chronic Non-tuberculous Infection of the Lungs. Speakers: Drs. Burrell, Chandler, Geoffrey Marshall, and Douglas Wilkinson, and Messrs. Tudor Edwards, J. E. H. Roberts, H. S. Souttar, Ewart Martin, C. A. S. Ridout, and V. E. Negus.

Section of Comparative Medicine.—Wed., 5 p.m., Dr. T. W. M. Cameron: The Parasites of Animals and Human Disease.

Section of Urology.—Thurs., 8.30 p.m., Mr. Graham S. Simpson: Haemangioma of the Kidney; Mr. F. J. F. Barrington: Nerve Supply of the Bladder.

Section for the Study of Disease in Children.—Fri., 4.30 p.m., Cases.

Section of Epidemiology and State Medicine.—Fri., 8 p.m., Dr. M. Greenwood and Dr. Janet Lane-Claypon: On the Possibility of Effecting a Reduction in the Present Mortality Rate from Cancer of the Breast and of the Uterus. Fleet Surgeon W. E. Home will show a Jenner letter and a portrait in oil of Francis Home (1719-1812).

MEDICAL SOCIETY OF LONDON, 11, Chandos Street, W.1.—Mon., 8.30 p.m., Pathological Evening.

MEDICO-LEGAL SOCIETY, 11, Chandos Street, W.1.—Thurs., 8.30 p.m., Dr. Halliday Sutherland: A Case concerning Survival in an Aeroplane Crash; to be followed by a discussion.

ST. JOHN'S HOSPITAL DERMATOLOGICAL SOCIETY (incorporating the London Dermatological Society), Leicester Square, W.C.2.—Wed., 4.15 p.m., Clinical Cases will be shown.

POST-GRADUATE COURSES AND LECTURES.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION, 1, Wimpole Street, W.—Special Lecture at the Medical Society of London, 11, Chandos Street, W., Thurs., 5 p.m., Haemoptysis. Free to members of the medical profession. *Chelsea Hospital for Women*, Arthur Street, S.W.: Tues., 2 p.m., Special Demonstration. Free to members of the medical profession. *Royal Northern Hospital*, Holloway Road, N.: Tues., 3.15 p.m., Lecture: Salpingitis. Free to members of the medical profession. *Bethlem Royal Hospital*, S.E.: Tues. and Sat., 11 a.m., Lecture Demonstrations on the Psychoses.

CENTRAL LONDON THROAT, NOSE, AND EAR HOSPITAL, Gray's Inn Road, W.C.1.—Fri., 4 p.m., Treatment of Chronic Suppurative Otitis Media.

HOSPITAL FOR SICK CHILDREN, Great Ormond Street, W.C.1.—Thurs., 4 p.m., Cataract in Infancy.

LONDON SCHOOL OF DERMATOLOGY, St. John's Hospital, Leicester Square, W.C.2.—Tues., 5 p.m., Erythrodermias. Thurs., 5 p.m., Electrotherapeutics.

NORTH-EAST LONDON POST-GRADUATE COLLEGE, Prince of Wales's General Hospital, Tottenham, N.15.—Mon., 10 a.m., Surgical Clinic; 2.30 to 5 p.m., Medical, Surgical, and Gynaecological Clinics; Operations Tues., 2.30 to 5 p.m., Medical, Surgical, Throat, Nose, and Ear Clinics; Operations. Wed., 2.30 to 5 p.m., Medical Skin and Eye Clinics; Operations. Thurs., 11.30 a.m., Dental Clinics; 2.30 to 5 p.m., Medical, Surgical, and Ear, Nose, and Throat Clinics; Operations. Fri., 10.30 a.m., Throat, Nose, and Ear Clinics; 2.30 to 5 p.m., Surgical, Medical, and Children's Diseases Clinics; Operations

POST-GRADUATE HOSTEL, Imperial Hotel, Russell Square, W.C.1.—Tues., 9 p.m., Pre-Listerian Surgery. Thurs., 9 p.m., Symposium: The Thyroglossal Tract.

ROYAL NORTHERN HOSPITAL, Holloway Road, N.—Tues., 3.15 p.m., Salpingitis. Tea at 4.15 p.m.

GLASGOW POST-GRADUATE MEDICAL ASSOCIATION.—At Eye Infirmary: Wed., 4.15 p.m., Eye Cases.

JAMES MACKENZIE INSTITUTE FOR CLINICAL RESEARCH, St. Andrews.—Tues., 4.15 p.m., Physiological Aspects of Blood Pressure.

SHEFFIELD UNIVERSITY POST-GRADUATE CLINICS.—At Royal Hospital: Fri., 3.30 p.m., Clinical Cases.

British Medical Association.

OFFICES, BRITISH MEDICAL ASSOCIATION HOUSE, TAVISTOCK SQUARE, W.C.1.

Departments.

SUBSCRIPTIONS AND ADVERTISEMENTS (Financial Secretary and Business Manager. Telegrams: Articulate Westcent, London).
MEDICAL SECRETARY (Telegrams: Mediscera Westcent, London).
EDITOR, *British Medical Journal* (Telegrams: Aitiology Westcent, London).

Diary of the Association.

JANUARY.

21 Fri. London: Joint Subcommittee on Combined Research by Insurance Practitioners, 2.30 p.m.
London: Maternity and Child Welfare Subcommittee, 2.30 p.m.
Leicester and Rutland Division: Medical Club, Bond Street, Leicester. B.M.A. Lecture by Mr. H. S. Souttar on the Clinical Aspects of Gastric and Duodenal Ulcers, 8.45 p.m.
23 Sun. Mid-Cheshire Division: Annual Meeting, Altrincham General ...
25 Tues. ... ry Committee, 2.30 p.m.
... dford County Hospital, 3 p.m.
... General Hospital. Sir Frank Colyer ... m.
Sunderland Division: Annual Meeting, Royal Infirmary, Sunderland, 8.15 p.m.
26 Wed. London: Journal Committee, 2.30 p.m.
Cardiff Division: Engineers' Institute, Cardiff. B.M.A. Lecture by Professor W. E. Dixon on the Trend of Thought in Modern Therapy.
North Middlesex Division: Discussion on Insulin.
Oxford Division: Radcliffe Infirmary, 2.45 p.m.
Salisbury Division: Museum Lecture Theatre, St. Ann Street, Salisbury. Dr. E. P. Poulton on the Therapeutic Value of Endocrine Gland Products, 8.15 p.m.
27 Thurs. North Suffolk Division: Lowestoft Hospital. The Medical Secretary on the Essentials of a Medical Organization, 4 p.m.
South Wales and Monmouthshire Branch: Clinical Meeting, Hotel Metropole, 3.30 p.m.
West Dorset Division: County Hospital, Dorchester, 8 p.m.
28 Fri. London: Medical Students and Newly Qualified Subcommittee, 2.30 p.m.
Bishop Auckland Division: Dr. A. T. Paterson on Some Common Ailments of the Eye.
Chesterfield Division: Maternity Hospital, Chesterfield. Professor J. S. C. Douglas on Passive Immunity, 8.15 p.m.
South Suffolk Division: Annual Meeting, Crown and Anchor Hotel, Ipswich, 3.30 p.m
31 Mon. London: Ophthalmic Committee, 3 p.m.

FEBRUARY.

1 Tues. London: Standing Ethical Subcommittee, 2.15 p.m.
Coventry Division: Mr. Baron T. Rose on Surgical Matters of Interest to General Practitioners.
Hastings Division: Queen's Hotel. Dr. F. C. Martley on Co-operation in Insurance for the Medical Profession, 8.15 p.m.
2 Wed. Nuneaton and Tamworth Division: Red Lion Hotel, Atherstone, 3.30 p.m.
3 Thurs. Guildford Division: Royal Surrey County Hospital, Guildford. Mr. T. P. Dunhill on the Diagnosis of Gall Stones, 3.45 p.m.
8 Tues. Reigate Division: East Surrey Hospital, Reigate. Sir W. Willcox on Fibrositis, 8.45 p.m.
St. Pancras Division: British Medical Association House, Tavistock Square, W.C.1., 9 p.m.
9 Wed. London: **Council**, 10 a.m.

BIRTHS, MARRIAGES, AND DEATHS.

The charge for inserting announcement of Births, Marriages, and Deaths is 9s., which sum should be forwarded with the notice not later than the first post on Tuesday morning, in order to ensure insertion in the current issue.

DEATHS.

LARKIN.—On January 13th, at his residence, Craven House, Grove Park, Kent, Frederick George Larkin, F.R.C.S.Eng. (Honorary), in his 80th year.

RIGDEN.—On January 15th, at his residence, Ingleside, Newnham-on-Severn, Glos, Brian Rigden, M.R.C.S., aged 70 years.

Printed and published by the British Medical Association, at their Office, Tavistock Square, in the Parish of St. Pancras, in the County of London.

The Hastings Popular Lecture
ON
CANCER AND HOW TO FIGHT IT.

DELIVERED IN THE GREAT HALL OF THE BRITISH MEDICAL ASSOCIATION ON JANUARY 24TH

BY

SIR BERKELEY MOYNIHAN, BT.,
PRESIDENT OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.

If the law of averages holds good, one hundred people in this room will die of cancer. Statistics, I was once courageous enough to claim, will prove anything, even the truth. The truth is that in this country one person in every seven, over the age of 30, dies of cancer, that 50,000 people die yearly in England and Wales, and that according to Hoffman 500,000 lives are annually lost in the civilized countries of the world from this disease. But the law of averages appears to be changing against us, for there is little doubt that cancer is definitely on the increase, especially in certain organs. Cancer is an ancient and a heartless foe. Examples of its lethal power are found in bones taken from the tombs near the pyramids of Egypt, dating from 3,500 years before Christ. It was known and described over twenty centuries ago by Hippocrates, the Father of Medicine, and it has never since ceased for one single day to take toll of precious lives.

A survey of the progress of medicine during this century shows that we are, little by little, but very surely, obtaining control over certain diseases which were formerly the plagues of mankind. In comparison with them cancer not only shows no decrease; it is actually gaining ground. Cancer is now the most dreaded, the most inexorable, the most menacing of all the physical infirmities of our race. It is the "Captain of the men of death." Let us give figures.

In the last twenty years—
The general death rate has fallen 32 per cent.
The infant death rate has fallen 45 per cent.
The tuberculosis death rate has fallen 38 per cent.
The cancer death rate has increased 20 per cent.

In the last seventy years the mortality from cancer has increased fivefold.

Attempts have been made to explain this increase in the death rate of cancer:

(*a*) By consideration of the fact that, the average expectation of life having increased, a larger number of people live to the cancer age, which is the period of life beyond 40 years. To some extent this is true; but the average duration of life is longer chiefly because of the lower infant mortality. Dr. Leonard Hill says:

"The expectation of life has gone up for infancy but not for the period of late middle age. There is no problem of what we are to do with our grandfathers, they are living scarcely any longer than they did fifty years ago."

(*b*) By ascribing it to increased accuracy of diagnosis. In this, too, there is truth. But if we pay regard to those cases in which diagnosis can never have been difficult, because the disease was near the surface and easily seen or felt, we find this argument is not sustained. For example, in cancer of the tongue there has been an increase of 39 per cent., and in cancer of the breast of 28 per cent., in the last twenty years. But it must also be remembered that some few diseases called cancerous in other days are now known to be simple. This is true of diseases of the stomach and of the large intestine.

This increased mortality from cancer, chiefly in the alimentary canal, has occurred despite the fact that more people than ever are being cured of cancer. It surprises many to hear that cancer can be cured; that the patient can be relieved for ever from his disease. But it is true. To-day operations of wide extent and of low mortality are more often followed by a permanent freedom from recurrence than they were twenty years ago. The operations practised to-day are more frequent, of greater extent, of greater safety, and attended by a larger measure of permanent relief from the disease than was the case twenty years ago. We are apt to hear of the failures of surgery as well as of its successes. Montaigne thought the doctor among the most fortunate of beings, because the sun shone upon his successes, while his failures were buried in the tomb. But this is not altogether true. We hear of deaths from operations, of recurrence from cancer after its removal; we hear little, even from the rescued, of their freedom from this disease. Cancer is rarely mentioned by those who have suffered from it; they appear to regard it as a sort of moral blemish, as something that is better not discussed, as something equivalent to idiocy or epilepsy in the family.

If it is true, as it is indubitably true, that permanent relief from cancer is being secured by our present methods in large numbers of cases, the question naturally arises as to why this is not more often possible. We are all a little to blame. Medical men are sometimes, though I am glad to think not very often, inclined to watch the earlier phases of this disease, especially when attacking internal organs, until it is certain that the condition is malignant. The certainty of diagnosis is often the certainty of death. If we wait until we know, we wait until we cannot cure. We must "look and see, know and act," and not "wait and see."

And the public is in part to blame; for among them there is great ignorance of the possibilities and the achievements of surgery, and ignorance is the parent of unbelief. What is the attitude of a patient who discovers a lump on the body, say a tumour in the breast? She says, "There is something wrong here; it may be cancer; if it is cancer I must undergo an operation; if I do I may die; if I survive, the disease may come back; if it returns I must submit once again to operation with all its risks; even then the disease may recur. It is a hopeless and

depressing prospect; I had better not mention the fact of the lump." And so time passes: the tumour grows and grows through every moment of every hour of every day, and at last the patient submits to a rescue operation, which the surgeon is reluctantly compelled to perform, knowing that he must do his best in adverse circumstances when precious time has been wasted, when the chances now are all against him. Unhappily, it is not very infrequent for the delay to be encouraged by the wasteful trial of other methods. The "cancer curer" is still a curse in the land, and the most pathetic credulity as to his claims is shown by people who should know better.

Cancer never yet was cured by the quack; but infinite harm has come to patients from the delay which foolish, impotent, and pernicious practices have involved—a delay which has allowed a small local disease to increase and to be strewn about the body. The desire for methods other than those which authority advises is as old as the days of Naaman, captain of the hosts of the King of Syria. When Elisha advised him to wash seven times in Jordan and so be cleansed of his leprosy, his wounded chauvinism made him cry out, "Are not Abana and Pharpar, rivers of Damascus, better than all the waters of Israel?" The sufferers from cancer are still beguiled by ignorant and pretentious quacks, and encouraged in their beliefs by irresponsible busybodies distinguished only by their complete ignorance of scientific method and their complete absence of scientific temper. Their statements are disputable in fact, doubtful in logic, and tend to betray the people whose lives must pay the penalty of their folly.

Who are the victims of cancer? A man's life has three stages: a stage of growth, of preparation for manhood and all its manifold activities; a stage of accomplishment, when all that he has learnt is applied to the purposes of his daily life; a stage of decline, when his vigour slowly wanes, his work is fulfilled. Cancer seizes a man, as a rule, in the later half of this second period, when his trained mind or hand is at its best; when his judgement has ripened; when his worth to his family and to the community is at its highest; when the service he can offer to the world is of greatest value; when knowledge grows to wisdom. This is the time for a man to live; the time to die is when work is done, when joy in labour has gone, when faculties are dimmed and enthusiasms quenched, when a man is no longer an asset to the world and has perhaps become an encumbrance even to himself. Cancer seizes a man when he is most needed by his family, who still ask a father's counsel and help, and is needed by the community for the service he can then best render.

Is it not, therefore, time for us to bestir ourselves, and to seek new sources of strength to fight this eager and relentless foe? To overcome an adversary we must make a study of his methods, inquire as to his origin, his designs, his power. If we have already encountered him we must discover both the circumstances in which we have been able to win a victory against him and the conditions under which we have suffered defeat.

What, then, do we know of cancer?

Cases of cancer may conveniently and for purposes of brief description be divided into two groups: First, those in which the growth is lying either on or near the surface of the body, or is attacking organs, or parts of organs, which can with no great difficulty or danger be removed. Secondly, those in which the growth is relatively inaccessible, lies out of sight, cannot be felt, and only reveals its presence by symptoms, or after examination by x rays. In these cases an operation may be difficult, impracticable, or even impossible.

How, then, can we expect to conquer or control this disease? It is obvious that two methods of attack must be followed.

In the first place we must so instruct the public and educate ourselves that those cases of cancer in which complete eradication of the disease is surgically possible shall be recognized and treated at the earliest moment. The operations now practised are reaching their limits, not only in extent and in the safety with which they can be performed by expert surgeons, but also in respect of the pain or discomfort they inflict. We cannot reasonably hope for any considerable change in any of these directions if the material upon which we work remain unchanged. We do, however, know that operations performed in the earliest stages of the disease are safer than those in the latest stages, when the patient's health seriously undermined by the disease, which may have spread insidiously beyond the farthest reach of the surgeon. We can make surgery safe, and even more successful, not so much by strengthening the arm of the surgeon as by enlisting the help of the patient; by encouraging him with the knowledge that accessible growths are capable of complete removal, with small risk, and with permanent freedom from recurrence, if only they can be reached in time.

And, in the second place, we must carry out all manner of research to disclose the secrets, the most baffling and elusive secrets, of the cause and the prevention of cancer, so that inaccessible cancer shall also be treated with success, or even prevented. We may even dare to hope that we are not far distant from the day when these mysteries will at last be revealed; when what is perhaps the heaviest burden ever laid upon mankind shall at last be lifted.

With regard to the education of the public there are certain disadvantages, some fanciful, some real. It is said that if we "talk cancer" we shall make people "think cancer." We hope that is true. We do not wish the public to "forget cancer." For cancer is an unforgiving enemy and once he has settled upon his victim, he never for one single moment ceases to grow, and the sooner you confront your foe the better for you and the worse for him.

It is said that we shall increase fear. That I firmly believe is impossible. The fear of cancer is so great in the minds of many people, if not in all, that it is impossible to add to it. Cancer is the King of Terrors. If we can help the public to learn that it is not cancer, but ignorance with regard to cancer that is in part responsible for their horror of it; and if we can assure them that cancer under certain conditions and when attacking certain organs is capable of complete removal with permanent freedom from a return of the disease, shall we not be able to diminish or even to banish fear? There is no evidence to show that cancer is bred by fear; that those who are fearful of its onset are especially liable to become its victims. Ignorance here, as elsewhere, is a part of fear; but fear does not contribute to the incidence of cancer. Fear should be the fear of delay, the fear lest a simple disease may become cancerous; the fear lest a local, and therefore curable, cancer should increase until it becomes generalized and incurable. Knowledge will bring freedom from fear. May I quote with warm approval a sentence from Mr. Hastings Gilford's book *Tumours and Cancers* (p. 601)?

> "A common impression is that it is not good for the public to concern itself about cancer. It is suggested that in this matter ignorance is better than knowledge—that it is better for people to remain in the dark than to let in the light. As a matter of fact we all know, when we think about it, that this attitude must be wrong. Cancer in reality is bad enough, but this bogie-hole way of treating the subject causes it to assume forms in the imagination more terrifying than they actually are."

Those of us who have been responsible for the Yorkshire Branch of the British Empire Cancer Campaign have realized the necessity of the education of the public. If surgery has almost reached the limit of its powers in removing disease, and if it is true that the earlier the disease the more effective is the operation in eradicating it, it is obvious that the recognition of an early stage of the disease cannot be made, and action thereon taken, until two consecutive events are secured—the awakening in the patient's mind of a need to consult the doctor, and action by the doctor, who in turn seeks aid from the surgeon. Unless, therefore, a patient knows something of the antecedent conditions of cancer, of its early manifestations, of the importance of early treatment, how is he to realize that a medical man should be consulted without the delay of one single day? Surgeons can hardly extend the limits of their work; but they may truthfully claim that if they are given a chance their present methods are capable, and that no other methods are capable, of effecting a permanent eradication of the growth in every case of accessible cancer. In Yorkshire I have "the happiness to command a band of brothers." The Medical and Scientific Com

mittee of the Yorkshire Council of the British Empire Cancer Campaign, over which I preside, has appointed a Propaganda Subcommittee, under the chairmanship of Dr. Hillman. This subcommittee will endeavour to instruct the public in such matters as it is essential for them to know if they are to help us, and will teach them to realize that the only hope of amelioration or of cure in cases of accessible cancer rests upon early diagnosis, and skilled surgical treatment.

Dr. Hillman writes to me:

"The Committee is to issue leaflets. Its members and others will give addresses to various local bodies; and will organize 'Exhibitions,' where microscope slides, graphic statistical charts, skiagrams, leaflets, striking 'posters,' and ingeniously described models will be shown. These Exhibitions are to be placed in charge of a qualified woman doctor who will give information to visitors and will answer any questions they may put to her. An hour each day will be devoted to 'women only,' and instruction is to be given in matters concerning tumours of the breast, irregular discharges, and so forth.

"Each 'Exhibition' is to be held in a vacant shop, centrally situated, and will last for one week; the arrangements for it are made in co-operation with local committees and with local medical officers of health. The demonstrations are purely educational and are not intended to raise funds.

"The subcommittee is now engaged upon a programme for taking these Exhibitions to the principal towns and villages in the county. If they prove successful, as they have already proved to be in two towns, it is intended to take a travelling exhibition on a motor lorry to the scattered villages.

"By these means it is intended to take a message of Hope to all who care to listen, and the subcommittee believes that a material lessening in the number of 'inoperable' cases will follow. It is a striking fact that at the first two Health Exhibitions held in Hull and Rotherham no less than 73,000 persons attended.

"The outstanding impression conveyed to the organizers was the keen and earnest desire for correct information manifested by those attending.

"Each Exhibition is to be opened by the local mayor, or other prominent citizen, and its existence is made known by leaflets distributed by boy scouts, clinic officials, and others), by illustrated slides at cinemas, and by pulpit references at all the places of worship.

"Interest has been stimulated by the demonstration of various electrical and other appliances, generously loaned by a surgical instrument firm, but all advice as to treatment has been studiously avoided. The only advice offered has been: 'Don't delay; don't conceal; be medically examined if you have the least suspicion that *anything* is wrong with you.'"

What are the lessons we can teach the public in connexion with this disease? The following are some of the truths it is important for them to know:

1. *Cancer a Local Disease at First.*

Cancer is always at first a local disease. This is an extremely important truth. For many years (and even to-day in the popular mind at least) the belief that cancer is a "blood disease" having local outbreaks is firmly held. In typhoid fever the general disease has its local manifestations. It is often supposed that the events in cancer are similar, that the blood is contaminated, and that the local evidence of this is the nodule or the ulcer, recognized as cancerous. All knowledge we possess refutes this view. Cancer begins locally; it remains local for periods that vary in length according to circumstances; it may even prove fatal while still local, and therefore, if accessible, still removable. There is no single exception to the truth that cancer in its beginning is a local disease.

2. *Diseased rather than Healthy Organs Attacked.*

Cancer chooses to attack a diseased rather than a healthy organ. It has been said that cancer never attacks a healthy organ, but that is to set the standard of health rather high. It is, however, quite certain that any organ, or the skin, when affected by some chronic disorder, is more apt to be attacked by cancer. This involves the necessity for us all, patients and doctors alike, to pay attention to health and to do all we can to keep fit. The majority of people, it may be said, commit suicide. If we consider the effect of alcohol, syphilis, tubercle; of the conditions which are set going by the rush for wealth, with all its attendant sacrifices of caution and prudence with regard to health from day to day, the statement, though shocking, appears to be true. St. Paul advises us to "keep innocence." We wish he had said "keep health," for sin is not seldom a synonym for disease.

3. *Cancer Influenced by Antecedent Conditions.*

The occurrence of cancer is influenced by antecedent conditions. The corollary to this is that cancer in certain instances may be regarded as a preventable disease. Sir Jonathan Hutchinson, many years ago, described what he called "precancerous conditions"—conditions which, *though not yet cancerous, would become cancerous*, or tend to become cancerous, if neglected. These are best seen upon the tongue. Cancer almost never develops upon a healthy tongue. The tongue affected is one which has suffered for many months or years from chronic superficial inflammation, due to syphilis, or smoking, or both; from cracks or fissures, or ulcers; or from denudation of its papillae by one cause or another. Chronic irritation is a definite precursor of cancer. This is seen especially upon exposed surfaces. Mule-spinner's cancer appears upon the lower parts of the abdominal wall in consequence of the protracted irritation of lubricating oil, and of repeated small injuries by the loom. Cancer was common in former days in chimney-sweeps; and "kangri cancer" in those living on the hills in Kashmir is caused by the wearing of a basket of burning fuel beneath the clothes. In those who work in aniline dyes cancer of the bladder appears far more frequently than in others.

4. *Cancer Uninfluenced by Certain Factors.*

The occurrence of cancer, so far as we know, is uninfluenced by certain factors, sometimes regarded as "causes."

(*a*) There does not appear to be any hereditary predisposition to cancer. The fact that one person in seven over the age of 30 dies from cancer must in this connexion be remembered. It implies that within the limits of slight variation from this normal the incidence in any family may appear to be unduly heavy. Probably few families of ordinary size escape cancer in three consecutive generations. Striking instances of the frequency of cancer in one or two generations of a family, and equally remarkable examples of its absence, come under observation from time to time. The work of Miss Maud Slye upon mice appears to show that a tendency to the development of cancer can be engendered by special breeding; but I cannot recognize any similar liability in man. The example of Napoleon and his relatives is often quoted in support of the contention that this disease "runs in families." But it is, we think, now generally admitted by those most competent to form an opinion, after an examination of his abdominal viscera, that Napoleon did not die of cancer.

(*b*) Cancer, so far as we know, is not caused by any special food or foods, nor by any absence of special foods. It is true that excessive indulgence in food when little or no exercise is taken will steadily and insidiously depreciate the general health; and that in such circumstances of lessened resistance a person may more easily fall a victim to cancer as to other diseases. Various articles of diet have been impugned—tomatoes, fresh meat, salt, and many others; but there is no evidence that would satisfy a scientific mind that these or any other articles of diet, in excess or in abstinence, play any specific part in causing this disease. The question of the effect of diet in cases of cancer has been much discussed; and a rather embittered controversy between the layman and a few medical stragglers on the one side, and the majority of the profession on the other, has not languished in recent years. It is true that a general supervision of a man's dietary when he is in health, or in illness, will often produce a sense of well-being and bring back a degree of vigour long forgotten. But, so far as we know, no change in the natural history of a malignant growth has ever been observed by competent authorities to result from such dietetic control in an indisputable case of carcinoma.

The Memorandum on Cancer issued by the Ministry of Health states (p. 3) that "it cannot be asserted with scientific authority that the use of any particular article of food increases the liability to cancer or prevents it from appearing." There appears to be no truth in the claim that restriction in diet or temporary starvation effects any real change in the disease; nor has any evidence that could satisfy a critically scientific judgement

been adduced to show that the cure of cancer, or its demonstrable subsidence or relief, is in the smallest degree dependent upon special systems of dietary. The Yorkshire Council of the British Empire Cancer Campaign are financing a new research upon this subject of diet in relation to cancer. Professor Mellanby of Sheffield has, with the consent of the University, undertaken this work, which could not be in more competent hands.

(c) There is at present no sufficient proof that "cancer houses" or "cancer districts" exist, though here again striking examples of individual exceptions to this statement may be observed. Further inquiry may well be conducted to resolve this question, and we are proposing to undertake a new survey of this matter in Yorkshire.

5. *Cancer neither Infectious nor Contagious.*

The disease is neither infectious nor contagious. Very few surgeons have ever seen any case in which transmission of the disease by contact could conceivably explain the development or localization of the disease.

6. *Spread by Direct Extension.*

The disease spreads from the spot originally affected by direct extension; by the invasion of lymphatic vessels, which then convey cancer cells to neighbouring glands and thence to distant parts; and rarely by invasion of the blood vessels and the transmission of cancer cells in the blood stream. The reverse procedure never occurs. That is to say, the disease never begins as a generalized systemic disease—as a "blood disease" having, in a later stage, a local manifestation.

7. *Pain Rare in the Early Stages.*

In the early stages cancer rarely causes pain. This is a truth which it seems very difficult for a patient to realize. One of the commonest incidents of practice is to hear a patient protest that a growth cannot be of a serious nature because no pain results from it. Perhaps few things surprise the surgeon more than the discovery of an advanced state of carcinomatous ulceration of the tongue. It seems impossible that a patient could tolerate the presence in the mouth of so repulsive a condition, one affected by every word of speech, by every movement of mastication and of deglutition; one capable of easy recognition by the patient, who has only to open his mouth in front of a mirror to realize the horror of the growth. Yet pain in the tongue, even when it is chafed and fretted by a jagged tooth, seems absent or inconsiderable; and when pain is present it is the ear, rather than the mouth, of which complaint is made. In tumours of the breast no pain, as a rule, is caused until the skin is involved; the lump is discovered by accident, and little regard is paid to it because it causes no inconvenience or discomfort. The truth that in women over 35 years of age a lump in the breast is malignant in three cases out of four needs all the repetition and emphasis that can be given to it. The silence of some forms of growth in the stomach and the rectum is notorious. In the alimentary canal it is often obstruction rather than discomfort that first attracts attention.

In cases of cancer ill health, anaemia, lassitude, distaste for food, and loss of weight are often regarded as the symptoms without which a diagnosis may hardly be made. In the earlier stages they are rarely present and are never conspicuous. The existence of carcinoma is compatible with perfect health, and in a few cases there may even be a gain in weight and a remarkable feeling of vigour and strength. "I never felt better in my life" is a statement often made by an incredulous patient who has just heard that he suffers from cancer. The symptoms now mentioned are significant, but they are apt to indicate a state of the disease which should be anticipated, if possible, by the discovery and eradication of the growth before they have time to appear.

8. *Cancer Curable when Local and Growth Accessible.*

While the disease is local and when the growth is accessible cancer is curable. This is a necessary and logical extension of the truth that cancer is invariably local in origin, and that it spreads from the point first attacked. While the disease is local the complete eradication, not only of the parts immediately involved, but of all the adjacent parts which are most likely to be first implicated in its extension, would also cure the disease. It is true that the patient might then live long enough to develop another type of cancer elsewhere; but the instances in which this has occurred are so rare as to be surgical curiosities, and of no importance in stating the truths of a general problem. There are, however, a large number of cases of carcinoma where the growths are not accessible to the surgeon, or lend themselves only to the most dangerous and least successful forms of attack.

The Control and Treatment of Cancer.

Our main reliance in the treatment of cases of cancer to-day is upon surgery. If a growth is accessible, and local, no other method than that of operation should be considered. The difficulty is to discover whether the disease, at the time the removal of the growth is contemplated, remains localized, or whether it has already extended to the primary glands, or perhaps has even spread beyond them. In many cases it is unhappily impossible to tell. Nothing could more clearly show the advantages of early operation, and the tragedy of neglect, than the statistics collected from the Leeds cases by Miss Gretta Wardle under the auspices of the Leeds Cancer Committee and published by the Ministry of Health. Here are the figures. The report deals with a series of 357 cases operated on in the General Infirmary and in the Hospital for Women and Children, Leeds, during the two periods 1910 to 1913 and 1919 to 1921. In every case the tumour has been submitted to microscopic examination. The cases have been analysed by Dr. Janet Lane-Claypon and classified on the following basis:

Class I.—Cases in which, so far as could be ascertained, the growth was entirely confined to the breast, the axillary glands not being involved.

Class II.—Cases in which the axillary glands were already invaded, but in which there was no evidence of involvement of any other neighbouring or distant organ or tissue.

Class III.—Cases in which either the adjacent or distant organs or tissues were involved—for example, the pectoral muscles, the skin when ulcerated, the cervical glands, the opposite breast, etc.

Excluding cases unclassified on account of insufficient clinical and pathological data, the following are the results of operation after three, five, and ten years respectively:

	Percentage Alive at		
	Three Years.	Five Years.	Ten Years.
Class I	89.6	85.1	71.4
Class II	36.3	18.5	5.2
Class III	28.0	13.5	5.6

If, however, the cases which died from the operation and those which died from other causes than recurrence of cancer be excluded the after-results are as under:

	Percentage Alive at		
	Three Years.	Five Years.	Ten Years.
Class I	94.0	91.3	87.5
Class II	38.1	20.0	5.8
Class III	31.1	15.1	5.5

The results for the complete operation of removal of the breast, pectoral muscles, and axillary contents (Rodman's or Halsted's operation) may be shown thus:

Class I.—Growth still local; 90.1 per cent. *alive* at ten years after operation.

Class II.—Axillary glands involved; 91.3 per cent. *dead* within ten years of operation.

Class III.—More advanced cases; 94.4 per cent. *dead* within ten years of operation.

For cases in Class I the number of survivors is within 14 per cent. of that shown in the general population table. They prove that cancer can be completely eradicated if the local growth is early and widely extirpated. They show that the degree of success depends upon the stage of the disease attacked by the operation. They are eloquent as to the need for haste, and as to the follies of delay.

The methods of surgery, however, are not always available. If the growth is inaccessible, or if a growth at one time accessible has by delay become disseminated, then no operation can eradicate the disease, and recourse must be had to other methods. Of these, by far the most valuable is the therapy of the deep x rays. From their skilled application the most remarkable results are occasionally observed. The retrogression of the disease, or even its disappearance for two or three years, does not justify the use of the word "cure." Though I have seen the most striking results—results which five years ago could not have been believed possible—I have never seen a patient "cured" by this treatment. The best testimony to the truth of this view of x-ray work is shown by the refusal or reluctance of the skilful radiologist to undertake treatment in any case in which surgical measures are possible. This means that only the cases in which surgery can do nothing are undertaken by the radiologist; and yet it is in these very advanced and otherwise hopeless cases that results are obtained which show the efficacy of the method.

In certain cases radium has its uses, and very remarkable temporary results are obtained. It is only, however, in cases of rodent ulcer, and by no means always even in them, that permanent freedom from recurrence has been observed. Cases of cancer of the tongue may show great improvement, and healing of a large and chronic ulcer may occur. Of the lead treatment of Blair Bell we cannot speak with certainty. But we know that a devoted and most earnest worker, with a scientific mind, and a scrupulous regard for sincerity and truth, is devoting his great talents, with an almost reckless disregard of his own time and his health, to the pursuit of what he believes to be a serious contribution to this grave problem. We must remember that his only chance of success is with the case in which everyone else has failed; with this category of the outcasts he has certainly done better than any man.

The points upon which we should at this moment concentrate our attention in our fight against cancer are, therefore, two:

1. To make the very utmost of our present methods, which are applicable to all cases of accessible growths.
2. To undertake research so that we may discover the cause or causes of cancer, and so be enabled to do something for the prevention of the disease, or for its cure by methods other than those of surgery.

We do not make the most of our present methods, and in my judgement we are not likely to make the most until the public is instructed in some of the matters essential for them to know if they are to seek help in that stage of the disease which is capable of cure. There are many medical men who regard with dismay or disapproval the suggestion that the public should be educated in matters concerning cancer. It is said we shall "frighten them to death." I prefer to think that we are frightening them to life. I do not believe we can increase the dread of cancer. I am sure we may easily diminish it by carefully worded instruction. The problem of cancer is so simple and straightforward that any intelligent person may understand it, and by understanding it learn to dread, not cancer, but neglect of cancer. And we must undertake research. We have learnt more of cancer during this century than in all the centuries that have gone before. It is perhaps hardly too much to say that the conquest of cancer is a question of money. Research, ceaseless research, by trained skilful workers; research of the widest kind into all aspects and relationships of the disease will surely capture the most elusive secret of its causation. In Yorkshire our appeals to the public for help have resulted in the collection of nearly £130,000 in twelve months. A research institute has been opened, and happily is associated with the University, under the direction of Dr. M. J. Stewart, professor of pathology, and of Dr. Passey, professor of experimental pathology and director of cancer research. All the scientific knowledge of the day is therefore accessible to our research workers. During the next decade I should like to see the most active and the most populous department of any research institute devoted to the study of the subject of cancer. Research in connexion with other diseases has within the last half-century saved millions of lives, released mankind from terrible sufferings, added immensely to human happiness and comfort, and helped to prolong the span of human life.

Research by Pasteur and Lister made possible the almost incredible advances of modern surgery, which have already saved more lives than all the wars of all the ages have thrown away. Research by Patrick Manson and Ronald Ross has given us the whole secret of malaria, and has shown how this disease, which has slain its millions, may be banished for ever from the earth.

Research has disclosed the mystery of yellow fever, and so made possible the building of the Panama Canal, converting a whole district that was a death-trap into a health resort.

Research has revealed the origin and mode of transmission of plague, the very name of which is still heard with horror. Plague is conveyed by the fleas which infest the rat. And so to-day we realize why in Babylon the snake and in Egypt the cat were sacred, were deified, and were worshipped. They devour rats and mice, and so keep away the plague.

Research has made us familiar with the cause of tuberculosis, and has enabled us to reduce the number of cases, the severity, and the mortality of enteric fever.

Research has done much to inform us of the mysteries of cancer. Dr. Gye, whose authority is indisputable, has said that "during the past twenty-five years, that is to say during the period of experimental research into this disease, there has been greater progress in the study of cancer than in the study of any other single serious malady that attacks human beings." We hope that research may discover the cause or causes of cancer and enable us perhaps even to prevent it, or to rescue its victims by some other method than that of operation. Cancer is the most formidable calamity afflicting mankind to-day. The enemy grows yearly in strength, and though we are defeating him in some of his strongholds, he is gaining on us elsewhere. The time has come for a great national uprising against him. And there are plain evidences that we are in deadly earnest in our efforts to subdue and destroy him.

For many minds, with many thoughts and many aims, are now uniting with a common watchword against a common foe. Victory will not come through the gates of dream. It will be won from a stubborn and relentless enemy by an army of ardent spirits who think no toil too heavy if spent in the service of humanity.

[An account of the Minister of Health's speech and of the discussion that followed the Hastings Lecture will be found in the body of the JOURNAL at page 207.]

British Medical Association.

CURRENT NOTES.

Some Work of the Week.

DURING the week ending January 22nd the following committees and subcommittees met: the Organization Committee on the 18th, the Building Committee on the 19th, the Office Committee on the 20th, and the Maternity and Child Welfare Subcommittee and a joint subcommittee dealing with the question of collective scientific research on the 21st.

The Organization Committee dealt with the usual routine business in connexion with central regulations, Division and Branch rules and boundaries, etc.; gave special consideration to the report of its Propaganda Subcommittee as to the position of some dormant Divisions; received a report that the agreement between the Association and the Medical Association of South Africa (British Medical Association) had been finally completed and that the first instalment of £1,000 had been sent as a contribution from the

home authorities towards the better organization of the Association in South Africa; dealt in a preliminary way with a resolution of the Representative Body directing an inquiry as to what extent and under what conditions financial and other assistance could be given to Branches and Divisions in the United Kingdom which might desire to invite societies formed for the promotion of the medical and allied sciences to hold conferences within the respective Association areas; and considered a proposed new method of dealing with certain sections of the membership of the Association which find difficulties in putting their views forward through the ordinary Association machinery.

The Building Committee spent the morning of January 19th in consideration of many important points that arise in connexion with the extension of the Association premises consequent upon the falling in of the leases of houses attached to the property. The Office Committee, on January 20th, dealt with many matters connected with the premises and with interdepartmental working arrangements, and also with proposed new arrangements with the press in regard to reporting the Annual Meeting Sections.

The Maternity and Child Welfare Subcommittee had before it strong representations from the Central Association for Mental Welfare, urging that the Government should be pressed to bring in and pass the Mental Deficiency Bill which was dropped, through lack of time and threatened opposition in the final stages, at the end of 1926; the subcommittee resolved to make representations to the Council in favour of such a course being taken by the Association. It considered the important questions raised by the growth of orthopaedic clinics throughout the country, and resolved to make representations thereon to the parent (Medico-Political) Committee; gave advice on several questions relating to maternity and child welfare clinics and school medical officer appointments referred to it; and had a report that, as a result of the action of the North Staffordshire Division, the four school medical officers of the Stoke-on-Trent county borough had received increases in their salaries, and that the school medical officer of the Plymouth county borough had also had an increase as a result of representations made by the Medical Women's Federation.

The Joint Subcommittee on Collective Medical Research is composed of representatives of the Insurance Acts Committee and of the Science Committee, and it had before it very interesting proposals suggesting the organization of collective medical research among general practitioners, in co-operation with the Ministry of Health. It arrived at certain provisional conclusions and decided to ask representatives of the Ministry of Health to meet it.

During the week the members of the central staff have dealt with many applications for advice on all sorts of professional questions. These applications extend over the whole range of medical practice, and are dealt with, as seems most appropriate, by the editorial, the financial, and medical departments. A feature that is growing is the frequency with which visiting oversea members ask for advice.

Death Certification: New Instruction to Registrars.

The Registrar-General has issued instructions to registrars that where they receive a death certificate in respect of a person who has not been seen by a doctor within fourteen days of death, they are to refer the fact to the coroner. This does not necessarily mean that an inquest will take place, because the coroner will doubtless generally be satisfied by his inquiries that there is no need for an inquest. It should be clearly understood that doctors are not under any obligation to see the body after death. When the public becomes acquainted with the new requirement doubtless they will frequently ask the doctor to make a special visit so that he may be in a position to certify that he has seen the dead body. If they do so, the doctor will, of course, be justified in charging a fee. It is to be expected that as a result of the new procedure there will be an increase in the number of certificates of the fact of death as observed by the doctor, a development which has always been favoured by the British Medical Association.

Association Notices.

BRANCH AND DIVISION MEETINGS TO BE HELD.

BIRMINGHAM BRANCH: COVENTRY DIVISION.—At the meeting of the Coventry Division, arranged for Tuesday, February 1st, Mr. Baron T. Rose will read a paper on "Surgical matters of interest to general practitioners."

BIRMINGHAM BRANCH: NUNEATON AND TAMWORTH DIVISION.—A meeting of the Nuneaton and Tamworth Division will be held at the Red Lion Hotel, Atherstone, on Wednesday, February 2nd, at 3.30 p.m. The meeting will be mainly a clinical and pathological one, and members are invited to show patients or specimens. Those who wish to do so are asked to communicate previously with Dr. Pracy, Colville House, Atherstone (telephone number, Atherstone 23), who is arranging the meeting. Patients should be in attendance from 3.30 to 3.45 p.m.

GLASGOW AND WEST OF SCOTLAND BRANCH: GLASGOW NORTH-WESTERN DIVISION.—A symposium on "Atmospheric pollution and its effect on health and environment" will be held in the Burgh Hall, Hillhead, on Wednesday, February 9th, at 8 p.m. Speakers: Mr. F. W. Harris, F.I.C., "Its intensity and methods of measurement"; Dr. W. G. Clark, "The influence of atmospheric pollution in the causation of acute and chronic lung affections"; Dr. Alex. Smith, "The therapeutic aspects of light"; Professor J. R. Currie, "Some other effects"; Baillie W. Brownhill Smith, "Preventive measures." A number of illustrative lantern slides will be shown.

METROPOLITAN COUNTIES BRANCH.—A meeting, to which are invited all fourth and fifth year students and recently qualified practitioners, will be held by the Metropolitan Counties Branch on Thursday, February 24th, at the British Medical Association House, Tavistock Square, London, W.C., when an address will be given by Mr. E. B. Turner, F.R.C.S., on "Practice and types of patients." Tea and coffee at 5 p.m.; address at 5.30.

METROPOLITAN COUNTIES BRANCH: CITY DIVISION.—The next meeting of the City Division will be held at the Metropolitan Hospital on Tuesday, February 1st, at 9.30 p.m., when Dr. Anthony Feiling will read a paper on "The clinical aspects of neuro-syphilis." A clinical meeting will be held at the same place on Friday, February 11th, at 4.30 p.m., when Mr. Peter Daniel, F.R.C.S., will speak. A Divisional fancy dress dance will take place on Thursday, March 24th, at the British Medical Association headquarters, Tavistock Square, W.C.

METROPOLITAN COUNTIES BRANCH: HAMPSTEAD DIVISION.—At the meeting of the Hampstead Division to be held on Thursday, February 10th, at 8.30 p.m., Mr. W. H. Trethowan, orthopaedic surgeon to Guy's Hospital, will read a paper on "Pain in the back."

METROPOLITAN COUNTIES BRANCH: HENDON DIVISION.—The next clinical meeting of the Hendon Division will take place at Hendon Cottage Hospital to-day (Friday, January 28th), at 8.30 p.m., when Professor R. T. Leiper, F.R.S., will deliver an address on "Some recent advances in parasitology."

METROPOLITAN COUNTIES BRANCH: KENSINGTON DIVISION.—A meeting of the Kensington Division will be held at the Kensington Palace Mansions Hotel, De Vere Gardens, W.8, on Wednesday, February 9th, at 8.45 p.m. Professor Leonard Hill, F.R.S., will read a paper entitled "Ultra-violet rays and their therapeutic value."

METROPOLITAN COUNTIES BRANCH: ST. PANCRAS DIVISION.—A meeting of the St. Pancras Division will be held at the British Medical Association House, Tavistock Square, W.C.1, on Tuesday, February 8th, at 9 p.m., when Dr. Webb-Johnson will speak on "Obesity: its causes and modern treatment."

METROPOLITAN COUNTIES BRANCH: SOUTH MIDDLESEX DIVISION.—A meeting of the South Middlesex Division will be held at St. John's Hospital, Twickenham, on February 9th.—8.15 p.m., general business; 8.30 p.m., paper by Dr. A. B. Porteous, assistant clinical bacteriologist, St. Mary's Hospital, on "Transfusion, immuno-transfusion of blood."

NORTH OF ENGLAND BRANCH.—The next scientific meeting of the North of England Branch will be held at the Royal Victoria Infirmary, Newcastle-on-Tyne, on Thursday, February 17th: 2.15 p.m., Mr. John Gilmour: "The problem of the spastic child"; 2.45 p.m., Dr. Wells Patterson: "Clinical evidence of subthyroidism"; 3.15 p.m., Mr. W. E. M. Wardill: "Some common conditions about the rectum and anus"; 3.45 p.m., tea; 4 p.m., Sir Robert Bolam: Dermatological cases; 4.30 p.m., Dr. Alex. McRae: "Sudden loss of sight."

NORTH OF ENGLAND BRANCH: SUNDERLAND DIVISION.—A meeting of the Sunderland Division will be held at the Royal Infirmary, Sunderland, on Wednesday, February 16th, at 8.15 p.m. Dr. A. Parkin will give an address on "Pleural effusion."

SOUTHERN BRANCH: PORTSMOUTH DIVISION.—*The next meeting* of the Portsmouth Division will be held at the Queen's Hotel, Southsea, on Thursday, February 10th, at 9.30 p.m., when Dr. James Collier, F.R.C.P. (London), will give an address on "Infantile paralysis." Supper, as usual, will be at 9 p.m. sharp; members intending to be present are requested to notify the honorary secretary, Dr. H. H. Warren, on or before Monday, February 7th.

SOUTH-WESTERN BRANCH: EXETER DIVISION.—The next meeting of the Exeter Division will be held in the Library of the Royal Devon and Exeter Hospital on Friday, February 4th, at 3.30 p.m. Lecture by Dr. R. V. Solly on "Some uses of the blood count in diagnosis and prognosis." Tea at 4.30. Business meeting at 5 p.m. Agenda: Report of Executive Committee as to the

scale of minimum commencing salaries for public health medical officers, and recommendation of executive to adopt resolution under Ethical Rules.

STAFFORDSHIRE BRANCH: SOUTH STAFFORDSHIRE DIVISION.—The second meeting of the session 1926-27 of the South Staffordshire Division will be held at the Victoria Hotel, Wolverhampton, on Tuesday, February 1st, at 8.15 for 8.30 p.m. Supper (tickets 3s. 6d. each, exclusive of wines) will be served at 8.30 prompt. Agenda: Lord Dawson of Penn, G.C.V.O., M.D., will deliver a lecture on "Some varieties of headache." Members of other Divisions will be welcome. Members who intend to be present at supper should notify the secretary forthwith.

SURREY BRANCH: GUILDFORD DIVISION.—A meeting of the Guildford Division will be held at the Royal Surrey County Hospital, Guildford, on Thursday, February 3rd, at 4 p.m. Agenda: Election of representatives and deputy representatives. Address by Mr. T. P. Dunhill on "The diagnosis of gall stones." Tea served at 3.45 p.m.

SURREY BRANCH: REIGATE DIVISION.—At the meeting of the Reigate Division to be held at the East Surrey Hospital, Reigate, on Tuesday, February 8th, at 8.45 p.m., Sir William Willcox, C.B., C.M.G., will speak on "The etiology and treatment of fibrositis (chronic rheumatism)."

SUSSEX BRANCH: BRIGHTON DIVISION.—The next meeting of the Brighton Division will take place at the Brighton Borough Sanatorium on Thursday, February 17th, at 3.45 p.m.

SUSSEX BRANCH: HASTINGS DIVISION.—The next meeting of the Hastings Division will be held at the Queen's Hotel, Hastings, on Tuesday, February 1st, at 8.15 p.m. Dr. F. C. Martley will read a paper on "The benefits of co-operation in insurance for the medical profession, and what has been done to supply it." The annual dinner will take place at the Royal Victoria Hotel, St. Leonards, on Friday, February 11th, at 7.30 for 7.45 p.m. (tickets 10s. 6d. each). Members are requested to notify the honorary secretary as soon as possible as to the number of tickets they will require for themselves and their guests.

YORKSHIRE BRANCH: DEWSBURY DIVISION.—A meeting of the Dewsbury Division will be held in the Man and Saddle Restaurant, Dewsbury, on Tuesday, February 1st, when Mr. E. R. Flint, F.R.C.S. (Leeds), will give an address on "The acute stomach." Coffee will be served at 8.15 p.m. Members from neighbouring Divisions will be welcome.

YORKSHIRE BRANCH: WAKEFIELD, PONTEFRACT, AND CASTLEFORD DIVISION.—A meeting of the Wakefield, Pontefract, and Castleford Division will be held at the Bull Restaurant, Westgate, Wakefield, on Thursday, February 10th. Dr. A. E. Barnes, senior honorary physician, Sheffield Royal Infirmary, will give an address on diet.

Meetings of Branches and Divisions.

BIRMINGHAM BRANCH: NUNEATON AND TAMWORTH DIVISION.

A MEETING of the Nuneaton and Tamworth Division was held on January 5th at the Nuneaton General Hospital. Mr. J. B. LEATHER, F.R.C.S., read a very interesting paper on "Abdominal injuries." He discussed the various factors that play a part in the causation of visceral injuries, and described the pathology and treatment of surgical shock in the light of the most recent research. He also entered into the question of diagnosis and treatment and the indications for operative intervention. His remarks were illustrated by records of actual cases. A discussion followed, and Mr. Leather replied to the various questions raised during the discussion. A vote of thanks to Mr. Leather was carried unanimously.

EDINBURGH BRANCH: SOUTH-EASTERN COUNTIES DIVISION.

AN ordinary meeting of the South-Eastern Counties Division of the British Medical Association was held on January 12th in the Railway Hotel, Newtown St. Boswells. Before the meeting was constituted the members remained standing while Dr. GEORGESON, chairman of the Division, intimated the death of their previous chairman, Dr. James M. Menzies of Selkirk. Dr. Georgeson said they all received a shock when they learned that Dr. Menzies, after an operation, had passed away on December 22nd last. He had been out on his rounds as usual two days before, visiting patients. Dr. Menzies was a beloved physician, his kindness and his faithfulness winning the respect of all who came into contact with him, and they in the South-Eastern Counties Division would miss his cheery face and his kind manner.

It was unanimously agreed that the Right Hon. the Earl of Home, Sheriff McAulay Smith, the Rev. Dr. M'Connachie, Sir Robert Philip, Dr. Drever, and Dr. Stevens should be invited to the annual dinner as the guests of the Division.

Dr. J. EASON gave a short address on the treatment of diabetes mellitus, which was listened to with great interest. At its conclusion Dr. Eason was thanked for his address.

SUSSEX BRANCH: BRIGHTON DIVISION.

A CLINICAL meeting of the Division was held at the Poor Law Institution, Brighton, on December 16th, 1926, when Dr. DONALD HALL was in the chair. Dr. H. J. MCCURRICH, medical officer to the institution, showed a most interesting series of cases, of which clinical notes in tabular form had been prepared for the use of members. This was followed by a discussion, and afterwards, on the suggestion of Dr. L. A. PARRY, a hearty vote of thanks to Mr. MCCURRICH and to all those who had assisted in carrying out the arrangements was carried with acclamation.

Naval and Military Appointments.

ROYAL NAVAL MEDICAL SERVICE.

Surgeon Captains R. W. G. Stewart, O.B.E., and T. W. Myles, C.B.E., to the *Victory* for R.N. Hospital, Haslar.

Surgeon Commanders M. Barton to the *Excellent*; G. G. Vickery, O.B.E., and G. Carlisle to the *Victory* for the R.N. Hospital, Haslar; C. F. Lynch to the *Ormonde* on recommissioning.

Surgeon Commanders G. B. Scott and J. C. Bringan, O.B.E., are placed on the retired list with the rank of Surgeon Captain.

Surgeon Lieutenant Commander H. C. A. Tandy-Cannon is placed on the emergency list, with original seniority of October 3rd, 1919.

Surgeon Lieutenant Commander E. B. Kelley to the *Champion*.

Surgeon Lieutenants J. H. Laydon to the *Princess Margaret*; R. W. Higgins and J. G. Holmes to the *Egmont* for the *Maine*; G. Phillips to the *Victory* for R.M. Infirmary, Portsmouth; H. M. Levy to the *Pembroke* for R.M. Infirmary, Chatham, temporary.

ROYAL ARMY MEDICAL CORPS.

The following Captains to be Majors: W. C. Hartgill, M.C., with precedence next below H. S. Milne, M.C.; J. H. Baird (prov.); F. Harris, M.C. (prov.).

ROYAL AIR FORCE MEDICAL SERVICE.

Squadron Leaders A. F. Rook to Headquarters, Irak; F. E. Johnson to Palestine General Hospital; R. S. Overton to the Basrah Combined Hospital, Irak; H. S. C. Starkey, O.B.E., to R.A.F. British Hospital, Irak.

Flight Lieutenants E. G. Howell to Palestine General Hospital; C. P. Barber to R.A.F. British Hospital, Irak.

Flying Officers W. O. McKeown to No. 203 Squadron, Egypt; E. J. Jenkins to No. 216 Squadron, Egypt.

The following are granted short-service commissions as Flying Officers for three years on active list: J. E. Foran, M. O'Regan.

REGULAR ARMY RESERVE OF OFFICERS.

ROYAL ARMY MEDICAL CORPS.

Lieut.-Colonels J. Matthews, D.S.O., and J. H. Campbell, C.B.E., D.S.O., having attained the age limit of liability to recall, cease to belong to the Reserve of Officers.

TERRITORIAL ARMY.

ROYAL ARMY MEDICAL CORPS.

Lieut.-Colonel J. W. Kemp, T.D., to be Brevet Colonel.

Captains to be Majors: R. W. Swayne, O.B.E., R. D. Cran, and R. A. Lennie.

To be Lieutenants: Second Lieutenant W. L. Kinnear, late 4/5th Battalion, Black Watch, with precedence as from May 4th, 1926; Lieutenant J. F. Fraser from General List, T.A., with precedence as from December 30th, 1925, and to be supernumerary for service with the Medical Unit, Aberdeen University Contingent, Senior Division, O.T.C.; R. A. M. Scott.

The announcement regarding Douglas Gordon Robinson which appeared in the *London Gazette* of November 26th, 1926, is cancelled.

VACANCIES.

ADELAIDE UNIVERSITY.—Elder Professorship of Anatomy. Salary £1,100 per annum.

BANCHORY SANATORIUM.—Medical Superintendent.

BERRINGTON HOSPITAL, near Shrewsbury.—Assistant Resident Medical Officer. Salary £200 per annum.

BIRMINGHAM AND MIDLAND EAR AND THROAT HOSPITAL.—Third House-Surgeon (non-resident). Salary £200 per annum.

BRADFORD MUNICIPAL GENERAL HOSPITAL.—House-Physicians and House-Surgeons. Salary £200 per annum each.

BRADFORD: ROYAL EYE AND EAR HOSPITAL.—Male House-Surgeon. Salary £120.

BRISTOL DISPENSARY.—Medical Officer (non-resident).

CAIRO UNIVERSITY.—Professor of Bacteriology. Salary £E.1,500 per annum.

CAMBRIDGE: ADDENBROOKE'S HOSPITAL.—Honorary Assistant Physician in charge of the Electrical and X-Ray Department.

CITY OF LONDON HOSPITAL FOR DISEASES OF THE HEART AND LUNGS, Victoria Park, E.2.—Assistant Surgeon.

COVENTRY CITY.—Assistant School Medical Officer (male). Salary £600 per annum, increasing to £700.

DERBYSHIRE EDUCATION COMMITTEE.—School Dentist. Salary £500 to £550 per annum.

EDINBURGH: ELSIE INGLIS MEMORIAL MATERNITY HOSPITAL, Abbeyhill.—(1) Senior House-Surgeon. (2) Two Junior House-Surgeons.

EDINBURGH HOSPITAL FOR WOMEN AND CHILDREN.—(1) Senior House-Surgeon. (2) Two Junior House-Surgeons. Salary at the rate of £25 per annum for (2).

EDINBURGH: ROYAL EDINBURGH HOSPITAL FOR SICK CHILDREN.—Five Honorary Resident Medical Officers.

ELIZABETH GARRETT ANDERSON HOSPITAL, 144, Euston Road, N.W.1.—Children's Physician.

ESSEX COUNTY HOSPITAL, Colchester.—(1) House-Physician. (2) Assistant House-Surgeon and Registrar. Males. Salary £150 and £120 per annum respectively.

GLOUCESTERSHIRE ROYAL INFIRMARY AND EYE INSTITUTION, Gloucester.—(1) House-Physician. (2) Assistant House-Surgeons. Males. Salary £150 and £120 per annum respectively.

HOSPITAL FOR SICK CHILDREN, Great Ormond Street, W.C.1.—Casualty Officer. Salary £400 per annum.

INVERNESS: NORTHERN INFIRMARY.—Senior House-Surgeon (male). Salary £120 per annum.

LIVERPOOL COUNTY BOROUGH.—Junior Assistant School Medical Officer. Salary £600 per annum.

LONDON JEWISH HOSPITAL, Stepney Green, E.1.—Assistant Surgeon in the Ear, Nose, and Throat Department.

NATIONAL HOSPITAL, Queen Square, W.C.1.—Registrar. Salary £200 per annum.

NEW ZEALAND GOVERNMENT.—Senior Assistant Medical Officers in the Mental Hospitals Department. Salary £640 (single men), £775 (*married*).

NORTHAMPTON GENERAL HOSPITAL.—Two House-Surgeons. Salary £150 per annum each.

OLDHAM ROYAL INFIRMARY.—House-Surgeon to Male Wards. Salary at the rate of £200 per annum.

QUEEN'S HOSPITAL FOR CHILDREN, Hackney Road, E.2.—Casualty Officer. Salary at the rate of £100 per annum.

ST. THOMAS'S HOSPITAL, S.E.1.—Surgeon in charge of Out-patients.

SHREWSBURY: ROYAL SALOP INFIRMARY.—(1) House-Surgeon. (2) House-Physician. Salary £250 and £160 per annum respectively.

SHROPSHIRE ORTHOPAEDIC HOSPITAL, Oswestry.—Junior House-Surgeon. Salary £150 to £250 per annum, according to experience.

SOUTH SHIELDS: INGHAM INFIRMARY.—Junior House-Surgeon (male). Salary £150 per annum.

SOUTHAMPTON: ROYAL SOUTH HANTS AND SOUTHAMPTON HOSPITAL.—Honorary Assistant Physician.

STAFFORDSHIRE GENERAL INFIRMARY, Stafford.—House-Physician (male). Salary at the rate of £150 per annum.

UNIVERSITY COLLEGE HOSPITAL.—Registrar at the Royal Ear Hospital, Huntley Street, W.C. Honorarium, £50 per annum.

UNIVERSITY COLLEGE HOSPITAL MEDICAL SCHOOL, W.C.1.—Demonstrator in Bacteriology (part-time). Salary £250 per annum.

WALTHAMSTOW URBAN DISTRICT COUNCIL.—Resident Medical Officer at the Hospital for Infectious Diseases, Chingford. Salary £300 per annum.

CERTIFYING FACTORY SURGEONS.—The following vacant appointments are announced: Walsall (Staffs), Portsoy (Banffshire), Rhynie (Aberdeenshire), Fenny Stratford (Bucks), Dumbarton (Dumbartonshire). Applications to the Chief Inspector of Factories, Home Office, Whitehall, S.W.1.

This list of vacancies is compiled from our advertisement columns, where full particulars will be found. To ensure notice in this column advertisements must be received not later than the first post on Tuesday morning.

APPOINTMENTS.

BENNETT, James, M.R.C.S., L.R.C.P.Lond., D.P.H., Medical Officer of Health, Lymm Urban District Council.

BROCKLEHURST, George L., M.B., B.S.Lond., D.P.H.Liverp., Medical Officer of Health and School Medical Officer, City of Canterbury.

STEEL, John P., M.B., Ch.B.Edin., Assistant Medical Officer and Deputy Superintendent, Cleveland Mental Hospital, Middlesbrough.

ROYAL WEST SUSSEX HOSPITAL, Chichester.—*Honorary Assistant Surgeons:* R. Brooke, M.B., B.S.Lond., F.R.C.S.Eng., and I. H. H. Gough, M.A.Cantab., M.R.C.S.Eng., L.R.C.P.Lond.

VICTORIA HOSPITAL, Burnley.—*Honorary Surgeons:* A. Callam, M.D.Aberd., and J. A. Mackenzie, Ch.M.Aberd.

DIARY OF SOCIETIES AND LECTURES.

ROYAL SOCIETY OF MEDICINE.

Section of Orthopaedics.—Tues., 5 p.m., Cases. 5.30 p.m., Clinical Meeting.
Section of p.m., Laboratory Meeting at the National W.C.1. Drs. D. McClean and E. O'Flynn: st to the Cerebro-spinal Fluid; Dr. E. Westor Hepatic Cirrhosis by Manganese; Dr. J. G. Greenfield: Haemofuscin in Nerve Cells; Dr. E. A. Carmichael: Types of Cerebral Glioma; Dr. J. G. Greenfield: Hortega Cells and their Pathological Alterations. Specimens of tuberous sclerosis and diffuse sclerosis will also be shown.
Sections of Tropical Diseases, Dermatology, and Therapeutics.—Wed., 5.30 p.m., Special Discussion on the Treatment of Leprosy. Speakers: Drs. J. M. H. MacLeod, J. H. Sequeira, Graham Little, G. Pernet, T. A. Hendry, E. Muir, H. W. Wade, C. B. Lara, Sir Leonard Rogers, and others.
Section of Laryngology.—Fri., 4 p.m., Cases.
Section of Anaesthetics.—Fri., 8.30 p.m., Mr. S. R. Wilson: Physiological Bases of Hypnosis and Suggestion, with special reference to anaesthesia.
Section of Otology.—Sat., 9.45 a.m., Cases. 10.30 a.m., Papers:—Dr. C. P. Symonds: Cerebral Abscess—Some Points in Diagnosis and Localization; Dr. Farquhar Buzzard: The Treatment of Traumatic Facial Paralysis.

HARVEIAN SOCIETY OF LONDON.—Clinical Meeting at Paddington Green Children's Hospital, Paddington Green, Thurs., 4.30 p.m.

RÖNTGEN SOCIETY, 32, Welbeck Street, W.1.—Thurs., 8.15 p.m., Dr. J. M. Woodburn Morison: The New Radiological Department of the Royal Infirmary, Edinburgh; Mr. H. D. Griffith: The Physics of Carbon Arc Therapy.

POST-GRADUATE COURSES AND LECTURES.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION, 1, Wimpole Street, W.1.—Special Lecture at the Medical Society, 11, Chandos Street, W.1, Thurs., 5 p.m., Complications of Gall Stones.* *London Temperance Hospital*, Hampstead Road, N.W.1: Special Clinical Surgery Demonstration, Mon., 2 p.m.* *Royal Westminster Ophthalmic Hospital*, Charing Cross, W.C.2: Special Clinical Ophthalmic Demonstration, Thurs., 5 p.m., Non-paralytic Squint and its Treatment.* *Royal Northern Hospital*, Holloway Road, E.: Tues., 3.15 p.m., Lecture and Demonstration on Laboratory Methods in Clinical Medicine.* *Bethlem Royal Hospital*, S.E.: Tues. and Sat., 11 a.m., Lecture Demonstrations on Psychological Medicine. *St. John's Hospital*, Leicester Square, W.C.2: Special Course in Dermatology. Instruction daily in the Out-patient Department at 2 and 6 p.m. Lecture on Tues., Alopecia, and on Thurs., Xanthoma, Herpes. *National Hospital*, Queen Square, W.C.1: Special Course in Neurology. Daily instruction, and special lectures. All information as to fees, etc., obtainable from the Fellowship of Medicine. Lectures marked * are open to all members of the medical profession without fee.

HOSPITAL FOR SICK CHILDREN, Great Ormond Street, W.C.1.—Thurs., 4 p.m., Demonstration of Surgical Cases.

LONDON SCHOOL OF DERMATOLOGY, St. John's Hospital, Leicester Square, W.C.2.—Tues., 5 p.m., Alopecia. Thurs., 5 p.m., Xanthoma, Herpes.

NATIONAL HOSPITAL, Queen Square, W.C.1.—Mon., Tues., Thurs., Fri., 2 p.m., Out-patient Clinics. Mon., 12 noon, Pathology of the Nervous System; 3.30 p.m., Some Effects of Head Injuries. Tues., 3.30 p.m., Syphilis as it affects the Nervous System. Thurs., 3.30 p.m., Polyneuritis. Fri., 12 noon, Anatomy and Physiology of the Nervous System; 3.30 p.m., Demonstration of Re-education Methods. Operations: Tues. and Fri., 9 a.m.

NORTH-EAST LONDON POST-GRADUATE COLLEGE, Prince of Wales's General Hospital, Tottenham, N.15.—Mon., 10 a.m., Surgical Clinic; 2.30 to 5 p.m., Medical, Surgical, nics; Operations. Tues., 2.30 to 5 p.m., Medica and Ear Clinics; Operations. Wed., 2.30 to 5 ; e Clinics; Operations. Thurs., 11.30 a.m., 5 p.m., Medical, Surgical, and Ear, Nose, and Throat, Nose, and Ear Clinics; 2.30 to 5 p.m., Surgical, Medical, and Children's Diseases Clinics; Operations. Fri., 10.30 a.m., Throat, Nose, and Ear Clinics; 2.30 to 5 p.m., Surgical, Medical, and Children's Diseases Clinics; Operations.

POST-GRADUATE HOSTEL, Imperial Hotel, Russell Square, W.C.1.—Mon., 6.30 p.m., General Meeting of Vice-Presidents and those interested in Post-graduate Work; 9 p.m., Our Duty to Colonial Visitors. Wed., 9 p.m., Parenteric Infections.

ROYAL NORTHERN HOSPITAL, Holloway Road, N.—Tues., 3.15 p.m., Demonstration of Laboratory Methods in Clinical Medicine.

WEST LONDON HOSPITAL POST-GRADUATE COLLEGE, Hammersmith, W.6.—Mon., 10 a.m. to 1 p.m., Genito-urinary Operations, Skin Department, Demonstration of Fractures; 2, p.m., Surgical Wards, Gynaecological and Eye Departments. Tues., 10 a.m. to 1 p.m., Lecture on Clinical Methods, Demonstrations in Venereal Diseases and Chest Cases; 2 p.m., Medical Wards, Throat, Nose, and Ear Department. Wed., 10 a.m. to 1 p.m., Children's Medical Out-patients, Medical Wards, Demonstration in Medical Pathology; 2 p.m., Surgical Wards, Eye Department. Thurs., 10 a.m. to 12 n [illegible] ; 2 p.m., Eye and Genito-urinary Depart Fri., 10 a.m. to 1 p.m., Gynaecological 1 Electrical Departments; 2 p.m., Throat, Sat., 10 a.m. to 1 p.m., Bacterial Thera lical Department. Daily: Operations, Med at 2 p.m.

GLASGOW POST-GRADUATE MEDICAL ASSOCIATION.—At Royal Hospital for Sick Children: Wed., 4.15 p.m., Surgical Cases.

JAMES MACKENZIE INSTITUTE FOR CLINICAL RESEARCH, St. Andrews.—Tues., 4 p.m. Heart-block.

SHEFFIELD UNIVERSITY POST-GRADUATE CLINICS.—At Royal Hospital: Fri., 3.30 p.m., Surgical Cases.

BIRTHS, MARRIAGES, AND DEATHS.

The charge for inserting announcement of Births, Marriages, and Deaths is 9s., which sum should be forwarded with the notice not later than the first post on Tuesday morning, in order to ensure insertion in the current issue.

BIRTHS.

WELLS.—On January 19th, at 153, High Street, Chorlton-on-Medlock, Manchester, to Nesta H. (*née* Perry), M.B., Ch.B., wife of Lionel W. Wells, A.C.G.I., a daughter.

WILSON.—On January 21st, at Farnborough, to Vera, wife of Major J. A. L. Wilson, R.A.M.C., a son.

MARRIAGES.

ARMSTRONG—FERGUSON.—On January 18th, 1927, at Fortwilliam Presbyterian Church, Belfast, by Rev. W. A. Watson, M.A., B.D., assisted by Rev. J. Humphreys, B.A. (uncle of the bride), Edward Armstrong, M.D., B.Sc., elder son of Mr. and Mrs. M. J. Armstrong, The Roddens, Larne, to Olive Ferguson, M.B., B.Ch., elder daughter of the late J. C. Ferguson, M.D., and Mrs. Ferguson, Lynford, Osborne Park, Belfast.

BEVAN—COMBE.—On January 22nd, at St. Peter's, Brockley, Frank Arthur Bevan, M.B., B.S., of Hadleigh, Essex, to Mary Combe of Brockley, London, S.E.

Printed and published by the British Medical Association, at their Office, Tavistock Square, in the Parish of St. Pancras, in the County of London.

THE VOLUNTARY HOSPITAL AND ITS FUTURE.*

BY

R. G. HOGARTH, C.B.E., F.R.C.S.,

SENIOR SURGEON, GENERAL HOSPITAL, NOTTINGHAM; PRESIDENT OF THE BRITISH MEDICAL ASSOCIATION.

WHEN I was asked to deliver the Hospital Sunday address, I accepted the invitation with the greater pleasure because of the compliment implied both to the British Medical Association, of which I have the honour to be President, and to the profession to which I belong.

The very name of Hospital Sunday reaffirms the intimate connexion between religion and medicine, which is almost as old as history itself. The common link is faith. Religion without faith is unthinkable; medicine without faith loses half its healing power.

Faith, therefore, is no new thing in medicine. It was once said, "He cures most in whom most have faith." The sufferer who casts his cares upon his doctor rids himself of a grievous handicap. Instead of obstructing the healing influence by his doubts and fears, he becomes submissive to it and may even quicken its work.

Hope vanishes when faith is checked. But faith in what? The choice is wide. It may be faith in the bottle of medicine. It may be faith in the little pill. It may be faith in the healing efficiency of water, hot or cold. It may be faith in the well advertised virtues of a patent medicine. It may be faith in a saint, or faith in a system, or faith in a book, or faith in a revelation. It may be faith in a master to whose message the ears of thousands are attuned while millions hear it not. Or it may be—such are the wonders of faith—faith in some plain humble doctor in a poor neighbourhood, who for a generation has gone about his business—and the Master's—of healing, unknown beyond the short radius of his daily activities, but within it respected, trusted, loved. Or, lastly, it may be that faith in faith itself, best understood in the Churches where the injunction "Only believe" has exercised on quiet receptive minds a soothing influence of healing, which passes the surface comprehension of the cynic but not the deeper understanding of the wise.

And now, lest you should think that I am leading you down rather misty paths, I will ask you as earnestly as I can for your active, positive faith in something which happily combines in itself many of the objects towards which faith is directed. I mean, of course, that great composite and complex institution the general hospital.

If you must have personality in which to believe, you will find it there on the hospital and nursing staffs. If you crave the strengthening atmosphere of place, which on the religious side you expect in shrine or temple, where is it better found than in the hospital from whose doors so many have gone forth healed and rejoicing? We do not hang our trophies on our walls, for trophies harbour dust, and dust is forbidden by the modern laws of health; but the records stand and are known, and the healed give us good report among their fellows. And if you desire—as who does not?—the comfort of hope to steady the shrinking of fear, from whose lips does it better proceed than from those of the doctor, who, subject himself to human infirmities, knows too much of pain to be niggardly of reasoned assurance and the salutary stimulus of a measured encouragement not to despair of returning health.

Perhaps you may think it strange if I go back four hundred years for a definition of the ideal hospital. Yet where is there a better than Sir Thomas More's, who in his Utopia conceived the hospital of his ideal city state to be so well appointed that "though no man is sent thither against his will, there is no sick person in all the city that had not rather lie in the hospital than at home in his own house"?

Consider what the hospitals were like when those words were written. They were the refuge of the destitute and the plague-stricken. At best they provided little more than a roof over the sick man's head and a mattress on which he might lie. Nursing there was none, and the medical art of the time was as often a hindrance as a help to recovery. Horrible contagions throve in the dark and reeking corners of the wards. The idea, therefore, of a hospital worthy of its name as a guest house where God's sick and poor are healed, so garnished and equipped that even the rich would rather lie there than at home, may well have seemed preposterous to More's contemporaries. Even to-day it requires something of an effort to break away from current conceptions, still far too circumscribed, of the function and scope of a general hospital.

So I invite you to conceive of your own General Hospital, here in Nottingham, as the hospital of the whole community in the wide area which it serves. Conceive it as the hospital, not of the poor alone, nor yet of the poor and the

* Delivered in the Albert Hall, Nottingham, on Sunday, January 30th, 1927.

wide range of the middle classes, but of all classes who are sick—all who care to use it, with no distinction of rich and poor. That is a new interpretation of the term "general hospital," and with your permission I will develop the idea.

But first I must guard against a *dangerous misconception*. I am not proposing to rob the poor of the least part of the birthright bequeathed to them by a long line of *magnanimous benefactors*. I say emphatically that, while you open the hospital door much wider to other classes, you must not close it one inch in the faces of the poor. The full freedom of the general hospital to the sick poor is the very origin and foundation of the voluntary system. For the poor the healing given by the hospital must still be without money and without price. But why, if nothing but the best is good enough for the poor, should less than the best be offered to others? Thus, while still maintaining the most generous definition of the poor and their poverty, I would ask all the rest to contribute to the hospital in proportion to their means with payments graded, not merely according to the total figure of the family income, but to the figure of its necessary expenditure, which, as you know, *is usually a totally different thing*.

No new principle is involved here. Payment for hospital treatment is already much more widespread than is commonly supposed. A recent official report has shown that 171 provincial hospitals, of which 27 are large institutions, make some provision to meet what is well described as the insistent demand for paying beds. The methods adopted vary widely. In some the payment is still disguised under the form of a thank-offering. Patients are told exactly what the cost of their maintenance has been, and then they are invited to give as generously as they can. I will only observe that no Chancellor of the Exchequer would dream of applying such a system to the income tax unless he was prepared for a gigantic deficit. In the hospitals it produces a useful, but quite inadequate, amount.

You will remember the poignant question in the New Testament, when, after the healing of the ten lepers, only one returned to give thanks—"But where are the nine?" I will not say that gratitude in the hospitals is expressed in the same unsatisfactory proportion. But you can well understand what happens. A patient who would cheerfully pay £100 to be cured when the pain is sharp upon him begins to think, as soon as the pain is gone, that perhaps he never was quite as bad as he feared; that Nature unaided might have healed him had he but left the cure to her; that £100 is a lot of money; that others are much better able to pay than he; that hospitals, *after all*, were designed to be free, and that if only they were run on business lines the expenses could certainly be cut down. And the result of all this hard thinking (*and there is* plenty of time to think in a hospital bed) is that if he gives £5 it is really all that he can afford. The plain moral, I take it, is that there should be a *definite contract* between hospital and patient as to what the patient shall pay.

Let us see how they arrange these matters in some of the American hospitals. Take that of Detroit, Michigan, where Mr. Henry Ford has his famous motor works. You will not be surprised to hear that Mr. Ford and his family have built and equipped a magnificent hospital with a school of nursing and hygiene attached. The hospital has 600 beds, and an out-patient department with a daily average of 300 patients. It is on a similar scale, in other words, to the Nottingham General Hospital. The Ford family have spent 10 million dollars on the land, buildings, and equipment, and they met the deficit on each year's working till the institution was complete. They have shown, as you will agree, a princely spirit of generosity. Now, waiving all claim to interest, they expect the patients who receive treatment to pay sufficient to cover current expenses. The room charges for board and nursing service vary from 4½ to 8 dollars a day, according to whether the patient shares a room with others or has a private room with bath. In addition he pays from 21 to 70 dollars a week for the professional services of physician or surgeon, according to the nature of his case, and there are other charges for *x*-ray or radium treatment and for special nursing if required. Even the out-patient department makes a first visit charge of 5 dollars for the routine physical examination and 5 dollars for the routine laboratory examination, and other charges are made at subsequent visits, according to treatment.

So it is clear that the Ford Hospital at Detroit is *specially designed for the patient who can pay*, and if the charges seem to us rather high, allowance must be made for the high wages and salaries of the United States, while if interest had to be paid on capital expenditure the charges would be much higher still. Half the beds—300 out of 600—are of the more expensive kind, with baths attached, at 8 dollars (or 32 shillings) a day, with a minimum professional charge of £4 and a maximum charge of £12 a week.

We have no hospitals like that in this country. Yet what a boon they would be to the middle classes, as offering a much needed alternative to the nursing home, which is an indispensable institution in our present system, but one which will, in my belief, eventually disappear when the transitional period is over and the paying hospital system is fully developed. For even the best of nursing homes are subject to the grave disability that they are run for profit. The city of Detroit, of course, has a *general hospital* as well where free treatment is offered to the poor; but the distinguishing feature of the Ford Hospital is that it is a *full-size hospital, equipped on the very latest lines*, advertising its attractions to the sick public just as a first-class hotel might, the crucial difference being that it is expected to return no other dividend than the improving health of its guests. The Bishop of Durham some time ago complained of the modern millionaire's lack of cultural imagination, even when obeying his benevolent impulses. This Ford Hospital is an effective answer to that charge, and I hope it may find many imitators.

If you do not altogether like the idea of a hospital run for paying patients only, though not run for profit, consider the scores of other hospitals in the United States, in Canada, and in this country too, where free and paying patients are found together under the same roof. The Liverpool Royal Infirmary has had five paying single-bed wards since 1887. There's the right principle; but fancy five paying beds for the whole of Liverpool! At Brighton there are fourteen private rooms, at Colchester twelve, and so on. The scale is utterly and grotesquely inadequate. In America the hospital exists as much for the paying as for the free patient. There you find part-paying patients and whole-payment patients, who pay for extra comforts and extra privacy according to a fixed tariff; nor is the fact concealed that such profit as is made on the paying patients is utilized for meeting the deficit on the free wards. The richer patients help to carry the poorer, which surely is just as it should be. They share all the incomparable advantages of a great hospital, which money cannot buy outside; and they are glad to help the poorer sufferers in the adjoining wards. Such a system is conceived in the true spirit of human fellowship in suffering; and, believe me, differences of class count for very little amid the stark realities of the operating table or in the hospital ward.

In my view we are ripe in this country for a rapid development of this system of mixed hospitals with paying and non-paying words, or, if it is preferred, for a system of twin hospitals, the one for free and the other for paying patients. The choice may often be determined by the possibilities of structural alterations on the existing hospital sites. Moreover, hospital experts now favour the view that a maximum of 600 beds is quite enough—or more than enough—for any general hospital, and that the model hospital of the future may be a large central building for urgent cases, with a ring of branch pavilions on the outskirts of the city to which cases may be cleared as soon as they can be moved. The motor car has made changes possible which twenty years ago would have been quite out of the question.

You will say, "What about finance?" I reply that such hospitals as I have described can be financed as our existing hospitals are financed—namely, by the voluntary subscriber. But he must be organized as never before. It must be brought home to every man and woman that if it is their misfortune to become hospital cases their place is in the hospital. When once people realize that when they are gravely ill their chance of making rapid recovery

is immeasurably greater in the hospital ward, they will not withhold their support. Given a liberal supply of paying wards, their subscriptions when in health will be sure, and in time of trouble they will gladly pay the tariff charged. We have to make the hospital to that extent a business proposition, just as at present the nursing home is a business proposition. But it will not be run for private profit—and that, I repeat, makes the all-essential difference.

May I remind you, in connexion with this problem of finance, that the provincial hospitals, as was shown by the last report of the Joint Council of the Order of St. John and the British Red Cross Society, are now doing remarkably well; 75 per cent. of 750 hospitals had a credit balance on their maintenance accounts for 1925, and their invested funds showed an increase of 6 millions in the last five years.

It is not a failing or a decaying system which can produce results like those. Remember, too, that 90 per cent. of the current expenditure is subscribed voluntarily, and only 10 per cent. is derived from public funds in return for services which the State or the public authorities could not render half so cheaply, even if they could do it as well. Let us get rid of the erroneous idea that the provincial hospitals live from hand to mouth under the threat of an ever-impending bankruptcy. It is not true. They were, indeed, in a parlous financial state after four years of war, during which they had most brilliantly justified their title to popular confidence and support. But that nightmare has passed away, and whenever you have a capable board of management you find the local general hospital facing the future with cheerful serenity. The problem of the great London hospitals, which have special difficulties of their own, must not be confounded with the problem in the provinces.

And what is the secret of this happy transformation? It is due mainly to the development of various contributory schemes, into which, unfortunately, I have no time to enter, to the better organization of workmen's contributions through their voluntary levies, and to the Hospital Savings Association and to the spread of the popular Hospital Saturday and Hospital Sunday movements. Not many years ago the bequests of the rich philanthropist and the annual subscriptions of the charitable were the mainstay of the hospitals. They are so no longer. It is not that rich benefactors give less, but that thousands of workmen now contribute their weekly pence. We have had many superb individual gifts in Nottingham, but the penny beats the pound every time when it rolls in by the million, and in the large provincial hospitals the income derived from the various kinds of contributory schemes is now double that of any of the four principal items of income. In our own county, for example, the contributions of the miners alone amounted in 1925 to £9,530. Last year's returns will show, I fear, a serious falling off, owing to the long stoppage in the industry, but I am confident that the Nottingham Hospital has no permanent source of income more assured and stable than that of the miners' levy.

Believe me, the key-word of the future is still "Voluntary contribution," which to my ear has a nobler and more humane sound than either tax or rate. It involves, I know, continuous effort on the part of a large band of voluntary workers. But though hospital workers may grumble at times, and wonder why they go on when others selfishly do nothing, they have their reward, which they deeply treasure in their hearts, though they may not often speak of it aloud. In a rather disillusioned world unselfish enthusiasm may become increasingly difficult to kindle. But the voluntary hospital, always advancing, sure of its goal, producing immediate as well as distant results, cheerful amidst suffering, mending the broken, restoring the rhythm of life to the sick, helpful always and invariably sympathetic, has never lacked good and loyal friends to champion its cause. Nor will it lack them in the days to come.

It is not unlikely that the friends of the voluntary hospitals have an anxious time before them in the near future in connexion with the approaching reform of the Poor Laws and the substitution of new public health committees of town and county councils for the existing boards of guardians. It looks as though the voluntary hospitals may be invited—happily there is no suggestion of compulsion—to place themselves under the direction of these public health committees, which would naturally take over control of the Poor Law infirmaries, and to receive in return additional grants of public money. Until the actual scheme is produced it would ill become me to pass judgement, but I am bound to say that the implications are a little alarming, so far as the independence of the voluntary hospitals is concerned, and the utmost vigilance and caution will be required. The freedom of the hospitals is their very life; from their freedom springs the joyous spirit which pervades them and the enthusiasm their cause inspires.

Just one more point as to the future of our Nottingham hospital. It lacks, to my mind, one thing above all for its completion, and that is a medical school and teaching staff. We have, as you know, an infant university, whose buildings are rising grandly above the old meadows of the Trent. We have still to kindle among our people a proper civic and intellectual pride in that inspiriting foundation. I look forward to the day when Nottingham University will possess amid its other faculties a Faculty of Medicine, and then it will need a medical school at the General Hospital. Do not, I beg you, consider this a matter of academic interest only. It is not so. Every large general hospital should have its medical school attached. No hospital fulfils its largest purpose unless it teaches as well as heals. Nothing contributes more powerfully towards keeping the resident and consultant staff of a hospital up to the highest mark of efficiency than the critical eyes of a band of eager students, quick to observe the failures as well as the successes of their instructors, and for ever comparing, contrasting, and asking the why and the wherefore. Doctors, like other people, give their best when most on their mettle. I must not enlarge on this theme on the present occasion, but I beg of you to consider it as a problem of real importance alike to Nottingham University and to the Nottingham General Hospital.

I ask you to believe, and to believe whole-heartedly, in the future of your General Hospital. Have faith in it, for it deserves your trust. There is no one on its staff, in whatever capacity, who does not give the best that he or she has to give. I ask you to work for its steady development along the safe, sure lines which have carried it to its present eminence, and to widen its sphere so that it may become a centre for the diffusion of medical and surgical science as well as a temple of healing. Above all, let us be content with nothing but the very best for the welfare of all our people and for the fame of the city and the county to which we are proud to belong.

British Medical Association.

CURRENT NOTES.

The Journal of the Medical Association of South Africa.

We welcome the first number of the *Journal of the Medical Association of South Africa* (British Medical Association), which, emerging from the fusion of two leading journals, the *South African Medical Record* and the *Medical Journal of South Africa*, signifies the union of two great organizations, and is a promise of the further progress of the medical profession in South Africa. The new journal is controlled by a committee consisting of the members of the Federal Council from the Cape (Western) Branch, and Mr. C. L. Leipoldt, F.R.C.S., and Dr. W. Darley-Hartley are the joint editors. In a foreword to the first number, which is dated January 8th, 1927, it is stated that, since the *Journal* is an official organ, its policy will be that of the controlling Association, and thus it will have behind it the weight of an assured authority. It is added that editorial responsibility is not excluded, nor will initiative be restrained, but both these qualities are likely to gain in strength from the close co-operation between the *Journal* staff and the officials of the Association. The essential importance of the help of the general practitioner is recognized, and an appeal is made for clinical notes, which may be written in English or in Afrikaans, since the new *Journal* is to be bilingual. Members of the Medical Association of South Africa will receive the paper

by virtue of their membership of the local Branches. The relatively small size of the early issues will probably be only a temporary feature, and we confidently predict a successful and useful career for the "J.M.A.S.A."

Some Work of the Week.

The special work of the week under review began on January 24th with Sir Berkeley Moynihan's Hastings Lecture on "Cancer and how to fight it"; an extension of the traditional policy of the Association with regard to public lectures rendered possible by the facilities afforded by the new premises. The lecture and discussion were fully reported in last week's BRITISH MEDICAL JOURNAL and SUPPLEMENT. The very wide publicity accorded to it by the lay press must have considerably enhanced its general utility. We feel, however, that the lecturer will share with other members of the Association our surprise at learning from one of our lay contemporaries that "there could have been no more severe reproof to the policy of 'Hush! Hush!' favoured by the British Medical Association than the lecture of Sir Berkeley Moynihan." This was not quite the impression most readers will have formed.

The committee work which is the basis of the report to be considered by the Council on February 9th was completed during the week by meetings of the Journal Committee and the Naval and Military Committee. The former was concerned mainly with points of detail, and more particularly with a number of those questions connected with advertisements which must always bulk largely in its work. Consideration of the number and variety of the interests covered by the advertisements in any one issue, and the points at which those interests touch the work of the profession and the Association, will be sufficient to show the complexity of the questions that arise. The Naval and Military Committee had before it a number of representations as to conditions in the medical services of the armed forces. The complaints came from several services and from widely different quarters, and the expediency of bringing such matters of personal hardship to the notice of the department concerned, in the interests alike of the individual and of his service, is by no means an easy matter to decide. The facts before the Committee on this occasion emphasized the increasing degree of co-ordination of the work of the several services. While medical officers subject to differing service regulations are called on to co-operate in the same or in similar pieces of work it is clear that many causes of complaint must arise, and equally clear that remedies will often be difficult to find. The Committee received a deputation from the League of Ex-Service Pharmacists, to whom it was able to extend its cordial support in their effort to secure that, at least in the larger military hospitals, qualified pharmacists shall in future be employed by the military authorities. In the past fifteen months the League has brought this matter before Parliament by means of questions.

In addition to the work of the two standing committees already mentioned a meeting of the Medical Students and Newly Qualified Practitioners Subcommittee has to be recorded. A general review of the work of Divisions and Branches in this connexion indicated the possibilities of the Council's scheme for covering this particular field, the outstanding fact being that in the case of two medical schools no less than 96 per cent. of the students who qualified and registered between October, 1924, and September, 1926, had been enrolled as members of the British Medical Association through the efforts of the Branch (Glasgow and West of Scotland) and Division (Newcastle-on-Tyne) concerned. The lowest return of enrolments, 23 per cent., came from an area where the Council's scheme has not yet been taken up locally. The difference between these two figures is a fair index to the value of efficiently organized local propaganda. Apart from this general review the attention of the Subcommittee was concentrated upon the essay competitions for final-year medical students, instituted in 1922. During the five years the average entry of essays has been twenty-six to twenty-seven; the number for the present year is twenty-five. For the purposes of the competition the medical schools are divided into fourteen groups, a prize of £10 being available for each group, and the Committee had to consider the reason for an entry as disappointing in quantity as it has been encouraging in quality. The two main faults found with the scheme have been that the subjects set have been unpopular and that the time allowed between the announcement of a competition and its closing date has been too short. As regards the first criticism, it may be pointed out that the five subjects selected have been various, and that any authoritative indication of a popular subject is yet to seek, the specific suggestions received up to date from the several medical schools showing little agreement as to the most suitable topics. As regards the second criticism, next year's entry will determine its validity, since the subject for competition for 1927-28—"What are the evidences of heart failure: describe signs and symptoms of any three cases you have personally examined"— was published last July. The full particulars of the competition for 1927-28 will be announced in the SUPPLEMENT very shortly. Mr. T. P. Dunhill, C.M.G., Dr. T. R. Elliott, C.B.E., D.S.O., F.R.S., Professor G. R. Murray, M.D., and Mr. G. Grey Turner, M.S., have kindly consented to act as examiners of the essays on "Three types of cases of thyroid enlargement with their treatment," submitted in the 1926-27 competition, the results of which will shortly be announced. It is hoped that the prizes for the six London groups of medical schools may be presented at a meeting for senior students and newly qualified practitioners on February 24th in the Great Hall of the Association's House. At this meeting Mr. E. B. Turner, F.R.C.S., will give an address on "Practice and types of patients." Arrangements for the 1928-29 competition are well advanced, and the subject will be declared shortly.

During the week the Medical Secretary addressed a very successful meeting of the North Suffolk Division at Lowestoft, speaking on the "Essentials of medical organization." The meeting was followed by a dinner.

A conference of no small interest to the profession as well as to the public was convened by the Labour party on January 28th, to discuss the problems of the nursing profession. The representatives nominated by the Council in connexion with this conference were Sir T. Jenner Verrall, Mr. H. S. Souttar, Dr. G. F. Buchan, and the Deputy Medical Secretary. A report appears in the JOURNAL this week at page 253.

Association Notices.

BRANCH AND DIVISION MEETINGS TO BE HELD.

CAMBRIDGE AND HUNTINGDON BRANCH.—A meeting of the Cambridge and Huntingdon Branch will be held at Addenbrooke's Hospital to-day (Friday, February 4th), at 2.30 p.m. Dr. J. Alden Wright will show a case of malignant endocarditis, and Mr. W. H. Bowen will read a paper on "Tuberculous glands in the neck," to be followed by a discussion.

DORSET AND WEST HANTS BRANCH: BOURNEMOUTH DIVISION.—The annual dinner of the Bournemouth Division will be held at the Royal Bath Hotel, on Thursday, March 3rd, and not as previously stated. It is hoped that members will keep this date free and will bring guests, including ladies.

ESSEX BRANCH: SOUTH ESSEX DIVISION.—A meeting of the South Essex Division will take place at the Palace Hotel, Southend, on Tuesday, February 8th, at 8.30 p.m., when Mr. B. Whitchurch Howell will deliver an address on "Orthopaedics of the lower limb, with special reference to fractures and splints." Dr. C. Grant Pugh, medical officer of health for the county borough of Southend, will address a meeting of the Division at the Palace Hotel, Southend, on Tuesday, March 8th, at 8.30 p.m.

GLASGOW AND WEST OF SCOTLAND BRANCH: GLASGOW NORTH-WESTERN DIVISION.—A symposium on "Atmospheric pollution and its effect on health and environment" will be held in the Burgh Hall, Hillhead, on Wednesday, February 9th, at 8 p.m. Speakers: Mr. F. W. Harris, F.I.C., "Its intensity and methods of measurement"; Dr. W. G. Clark, "The influence of atmospheric pollution in the causation of acute and chronic lung affections"; Dr. Alex. Smith, "The therapeutic aspects of light"; Professor J. R. Currie, "Some other effects"; Baillie W. Brownhill Smith, "Preventive measures." A number of illustrative lantern-slides will be shown.

GLASGOW AND WEST OF SCOTLAND BRANCH: LANARKSHIRE DIVISION.—A meeting of the Lanarkshire Division will be held at the County Hospital, Motherwell, on Tuesday, February 22nd, at 8.30 p.m., when Dr. John Reid will read a paper entitled "The fever hospital and the practitioner."

GLOUCESTERSHIRE BRANCH.—The February meeting of the Gloucestershire Branch will be held at the Royal Infirmary, Gloucester, on Thursday, February 10th, at 6 p.m. Preliminary Agenda: Report of Branch Council as to the scale of minimum commencing salaries for public health medical officers, and recommenda-

tion to adopt resolution under Ethical Rules. Supper at the Spread Eagle Hotel will take place after the meeting (5s. each, exclusive of wine). Members intending to be present at the supper are asked to notify Dr. W. Arnott Dickson, honorary secretary.

KENT BRANCH: ROCHESTER, CHATHAM, AND GILLINGHAM DIVISION.—The annual general meeting of the Rochester, Chatham, and Gillingham Division will take place at the Bull Hotel, Rochester, on Friday next, February 11th. Dinner, at 7.30 p.m., will precede the meeting. The agenda includes election of officers. In place of the usual paper several members will give brief accounts of cases of interest (limited to five minutes), and will invite discussion on them. The price of dinner will be 10s. 6d., exclusive of wine. Dinner jackets will be worn. Members may invite guests. Those intending to be present are asked to write to the honorary secretary, Dr. Myles Tonks, Manor House, Old Brompton, Chatham, before Wednesday, February 9th.

LANCASHIRE AND CHESHIRE BRANCH: HYDE DIVISION.—At the meeting of the Hyde Division to be held in the Stalybridge Town Hall on Thursday, February 24th, at 8.30 p.m., an address will be delivered by Dr. F. Craven Moore of Manchester.

LANCASHIRE AND CHESHIRE BRANCH: MANCHESTER DIVISION.—A meeting of the Manchester Division will be held to-day (Friday, February 4th), at 8 for 8.30 p.m., at the Out-patient Department of the Royal Manchester Children's Hospital, Gartside Street (off Quay Street), Manchester. Refreshments will be served at 8 p.m. The medical and surgical staff of the hospital have arranged the following programme: (1) The artificial sunlight department will be on view and demonstrations given. (2) The massage and orthopaedic department will be shown. (3) Demonstration of the urea concentration test for nephritis. (4) Pathological specimens of interest. (5) Radiograms. (6) Two short papers: (9.30 p.m.) "Treatment of hare-lip"; (9.50 p.m.) "Infections of the urinary tract in children." It is hoped that every member will make a special effort to be present.

METROPOLITAN COUNTIES BRANCH.—A meeting, to which are invited all fourth and fifth year students and recently qualified practitioners, will be held by the Metropolitan Counties Branch on Thursday, February 24th, at the British Medical Association House, Tavistock Square, London, W.C., when an address will be given by Mr. E. B. Turner, F.R.C.S., on "Practice and types of patients." Tea and coffee at 5 p.m.; address at 5.30.

METROPOLITAN COUNTIES BRANCH: CITY DIVISION.—A clinical meeting of the City Division will be held at the Metropolitan Hospital on Friday, February 11th, at 4.15 p.m., when Mr. Peter Daniel, F.R.C.S., will speak. A Divisional fancy dress dance will take place on Thursday, March 24th, from 8.30 p.m. to 1.30 a.m., at the British Medical Association headquarters, Tavistock Square, W.C. Tickets 8s.

METROPOLITAN COUNTIES BRANCH: HAMPSTEAD DIVISION.—At the meeting of the Hampstead Division to be held at the Hampstead General Hospital on Thursday, February 10th, at 8.30 p.m., Mr. W. H. Trethowan, orthopaedic surgeon to Guy's Hospital, will read a paper on "Pain in the back."

METROPOLITAN COUNTIES BRANCH: KENSINGTON DIVISION.—A meeting of the Kensington Division will be held at the Kensington Palace Mansions Hotel, De Vere Gardens, W.8, on Wednesday, February 9th, at 8.45 p.m. Professor Leonard Hill, F.R.S., will read a paper entitled "Ultra-violet rays and their therapeutic value."

METROPOLITAN COUNTIES BRANCH: LEWISHAM DIVISION.—At a meeting of the Lewisham Division to be held at the Town Hall, Catford, S.E.6, on Tuesday, February 15th, at 8.15 p.m., Dr. Alfred Cox, the Medical Secretary, will deliver an address on "The medical profession in South Africa."

METROPOLITAN COUNTIES BRANCH: NORTH MIDDLESEX DIVISION.—At the meeting of the North Middlesex Division to be held on Wednesday, February 23rd, Mr. Reginald C. Holmes, M.R.C.V.S., will read a paper on "Some diseases of interest to both medical and veterinary professions."

METROPOLITAN COUNTIES BRANCH: ST. PANCRAS DIVISION.—A meeting of the St. Pancras Division will be held at the British Medical Association House, Tavistock Square, W.C.1, on Tuesday, February 8th, at 9 p.m., when Dr. Webb-Johnson will speak on "Obesity: its causes and modern treatment."

METROPOLITAN COUNTIES BRANCH: SOUTH MIDDLESEX DIVISION.—A meeting of the South Middlesex Division will be held at St. John's Hospital, Twickenham, on February 9th.—8.15 p.m., general business; 8.30 p.m., paper by Dr. A. B. Porteous, assistant clinical bacteriologist, St. Mary's Hospital, on "Transfusion, immunotransfusion of blood."

METROPOLITAN COUNTIES BRANCH: WILLESDEN DIVISION.—A meeting of the Willesden Division will be held at the Willesden General Hospital, Harlesden Road, N.W.10, on Wednesday, February 16th, at 9 p.m. Mr. D. C. L. Fitzwilliams will read a paper on the tongue.

MIDLAND BRANCH: CHESTERFIELD DIVISION.—A meeting of the Chesterfield Division will be held at the Maternity Hospital, Chesterfield, on Friday, February 25th, at 8.15 p.m. Dr. Miles Phillips, professor of midwifery, University of Sheffield, will give an address on "Gynaecological diagnosis."

NORTH OF ENGLAND BRANCH.—The next scientific meeting of the North of England Branch will be held at the Royal Victoria Infirmary, Newcastle-on-Tyne, on Thursday, February 17th: 2.15 p.m., Mr. John Gilmour: "The problem of the spastic child"; 2.45 p.m., Dr. Wells Patterson: "Clinical evidence of subthyroidism"; 3.15 p.m., Mr. W. E. M. Wardill: "Some common conditions about the rectum and anus"; 3.45 p.m., tea; 4 p.m., Sir Robert Bolam: Dermatological cases; 4.30 p.m., Dr. Alex. McRae: "Sudden loss of sight."

NORTH OF ENGLAND BRANCH: BISHOP AUCKLAND DIVISION.—At the meeting of the Bishop Auckland Division to be held on Friday, February 25th, Dr. Farquhar Murray (Newcastle-on-Tyne) will read a paper on "Some modern aspects of midwifery and gynaecology."

NORTH OF ENGLAND BRANCH: SUNDERLAND DIVISION.—A meeting of the Sunderland Division will be held at the Royal Infirmary, Sunderland, on Wednesday, February 16th, at 8.15 p.m. Dr. A. Parkin will give an address on "Pleural effusion."

NORTH OF ENGLAND BRANCH: NORTH NORTHUMBERLAND DIVISION.—A meeting of the North Northumberland Division will be held in the Alnwick Infirmary on Tuesday, February 8th, at 2.30 p.m. Agenda: Annual report of Division; election of representative. After the meeting an address, illustrated with lantern slides, will be given by Mr. Norman Hodgson, entitled "Injuries to the hand and their treatment." Tea will be provided.

NORTHERN COUNTIES OF SCOTLAND BRANCH.—A clinical meeting arranged by the Northern Counties of Scotland Branch will be held at Gray's Hospital, Elgin, on Friday, February 18th, at 3 p.m.; tea at 4.30.

SOUTH WALES AND MONMOUTHSHIRE BRANCH: SWANSEA DIVISION.—The following programme has been arranged by the Swansea Division:—February 24th: British Medical Association Lecture by Dr. Robert Hutchison, followed by a supper; March 10th: Short papers; March 24th. General clinical meeting; April 7th: Discussion on appendicitis, to be opened by Dr. Daniel E. Evans (medical), Mr. Howell W. Gabe (surgical), Dr. A. F. S. Sladden (pathological), and Major W. P. Gould Williams (radiological), each opener limited to fifteen minutes; June 30th (provisionally): Annual meeting. The meetings will be held at the General Hospital, Swansea, at 8.15 p.m., except the British Medical Association Lecture on February 24th. Members desirous of reading papers or of showing cases and specimens are requested to communicate with the honorary secretaries not later than seven days before the date of next meeting.

SOUTHERN BRANCH: PORTSMOUTH DIVISION.—The next meeting of the Portsmouth Division will be held at the Queen's Hotel, Southsea, on Thursday, February 10th, at 9.30 p.m., when Dr. James Collier, F.R.C.P. (London), will give an address on "Infantile paralysis." Supper, as usual, will be at 9 p.m. sharp. members intending to be present are requested to notify the honorary secretary, Dr. H. H. Warren, on or before Monday, February 7th.

SURREY BRANCH: CROYDON DIVISION.—A meeting of the Croydon Division will be held at the Croydon General Hospital on Tuesday, February 22nd, at 8.30 p.m., when Professor Leonard Hill, F.R.S., will discuss "Sunshine and open air."

SURREY BRANCH. REIGATE DIVISION.—At the meeting of the Reigate Division to be held at the East Surrey Hospital, Reigate, on Tuesday, February 8th, at 8.45 p.m., Sir William Willcox will speak on "The etiology and treatment of fibrositis (chronic rheumatism)."

SUSSEX BRANCH: BRIGHTON DIVISION.—The next meeting of the Brighton Division will take place at the Brighton Borough Sanatorium on Thursday, February 17th, at 3.45 p.m.

SUSSEX BRANCH: HASTINGS DIVISION.—The annual dinner of the Division will take place at the Royal Victoria Hotel, St. Leonards, on Friday, February 11th, at 7.30 for 7.45 p.m. (tickets 10s. 6d. each). Members are requested to notify the honorary secretary as soon as possible as to the number of tickets they will require for themselves and their guests.

YORKSHIRE BRANCH: BRADFORD DIVISION.—On Wednesday, February 23rd, Mr. N. Bishop Harman will deliver a British Medical Association Lecture to the Bradford Division entitled "The recognition of common eye disorders in general practice." The lecture will be given at the Royal Infirmary at 8.30 p.m.

YORKSHIRE BRANCH: WAKEFIELD, PONTEFRACT, AND CASTLEFORD DIVISION.—A meeting of the Wakefield, Pontefract, and Castleford Division will be held at the Bull Restaurant, Westgate, Wakefield, on Thursday, February 10th. Dr. A. E. Barnes, senior honorary physician, Sheffield Royal Infirmary, will give an address on diet.

Meetings of Branches and Divisions.

BIRMINGHAM BRANCH: WEST BROMWICH DIVISION.

THE annual meeting of the West Bromwich Division was held on January 11th, when the retiring CHAIRMAN gave a summary of the work of the Division during 1926.

The following officers were elected for the current year:

Chairman, Dr. J. P. McVey. *Vice-Chairman*, Dr. A. B. Hamilton. *Honorary Secretary*, Dr. J. M. Mitchell. *Representative in Representative Body*, Dr. J. M. Mitchell. *Deputy Representative in Representative Body*, Dr. J. H. Hartland.

The programme for 1927 was approved, as follows: In April Dr. Lewis Graham of Birmingham will read a paper on "Some points in the conduct of midwifery in private practice." In June a clinical meeting will be held at the District Hospital, West Bromwich, when members will be entitled to show cases, and, if desirous of doing so, should arrange with one of the honorary surgeons. In October Dr. W. A. Potts of Birmingham will read a paper on "Psycho-analysis" at Smethwick. The proposal that Rule 12 (1) should be altered to read "ordinary meetings of the Division shall be held during the months of January, April, June, and October (three meetings in West Bromwich, one meeting in Smethwick)" was carried unanimously.

It was reported that the formation of a local hospitals committee was now nearly complete. Dr. L. A. Dingley and Dr. A. L. Bodley had been appointed to represent the District Hospital,

West Bromwich, and Dr. Hamilton to represent the Fever Hospital; the two representatives for Hallam Hospital would be appointed shortly.

The need for increased support for the medical charities was impressed on the members. In view of the fact that a memorandum on the subject would shortly be issued from headquarters, the matter was left over till the April meeting, when a definite policy for the Division would be brought forward.

An interesting paper on "The vagaries of the Health Insurance Act" was read by the CHAIRMAN.

CEYLON BRANCH.

A MEETING of the Ceylon Branch was held in the Colonial Medical Library on October 13th, 1926. Dr. G. COOKE showed three interesting cases—(*a*) ventral hernia, (*b*) ventral hernia complicating second pregnancy, (c) large ovarian cyst following an operation performed two years previously. Dr. S. CHELLIAH read a paper on "Rabies and hydrophobia." Votes of thanks were accorded to the readers of the papers and to the chairman.

A further meeting of the Branch was held in the Colonial Medical Library on November 10th, when Dr. A. RAJASINGHAM read a paper on the views of a new French school on dietetics and therapeutics, and communicated notes regarding the treatment of mumps. Dr. H. O. GUNEWARDENE read notes on a case of so-called hepatic intermittent fever, and Dr. G. S. SINNETAMBY on a case of ainhum. The meeting terminated with a vote of thanks to the chairman and to the readers of the papers.

The annual general meeting of the Ceylon Branch took place in the Colonial Medical Library on December 15th. The report of the Council for the year 1926 was read and adopted, and the audited statement of accounts was submitted and approved.

The following officers were elected for 1927:

President, The Hon. Dr. J. F. E. Bridger. *President-Elect for 1928*, Dr. V. Van Langenberg. *Vice-Presidents*, Drs. A. Rajasingham and S. Muttiah. *Honorary Secretary and Treasurer*, Dr. H. O. Gunewardene.

A programme of monthly meetings of the Branch was approved, and votes of thanks were accorded to the retiring officers.

NORTH OF ENGLAND BRANCH: DARLINGTON DIVISION.

A CLINICAL meeting of the Darlington Division was held at Greenbank Hospital, Darlington, on January 13th. Dr. H. C. PEARSON presided, and there was a fair attendance. The speaker of the evening was Dr. J. LE FLEMING BURROW, who chose for his subject "Recent advances in diagnostic methods." He dealt principally, and in a most convincing manner, with the urea concentration test, fractional test meal examinations, blood sugar tests, and x-ray examination of the stomach. A discussion followed, after which a very hearty vote of thanks was accorded to Dr. Burrow for his excellent address.

SOUTHERN BRANCH: PORTSMOUTH DIVISION.

THE *souper dansant* arranged by the Portsmouth Division, and held at the Esplanade Assembly Rooms, Southsea, on January 11th, proved an unqualified social success. Over 350 guests attended, the dancing floor and band were excellent, the novelties amusing, and as the all-pervading spirit from start to finish was one of jollity and good humour the result was one of the most enjoyable social functions of the season. The arrangements, which were in the hands of the honorary secretary, Dr. H. H. Warren, gave unusual satisfaction. After paying all expenses there remained a balance of £30 for medical charities.

SUFFOLK BRANCH: NORTH SUFFOLK DIVISION.

A MEETING of the North Suffolk Division was held at the Lowestoft Hospital on January 27th, when Dr. CANE presided. There was a good attendance, including members from the Norwich and East Norfolk Divisions.

Dr. ALFRED COX (Medical Secretary of the Association) gave a very interesting and valuable address, entitled "The essentials of a medical organization." Tracing the development of trade unions, Dr. Cox showed how the members of the medical profession were becoming increasingly under the control of the Government or of some public authority, and proceeded to contrast the fundamental differences between the trade union of the working man and the organization necessary for a body of professional men. He urged the need for organization because of the contractual relations of an increasing number of medical men with public bodies, and he detailed the principles of such an organization. Dr. Cox foreshadowed big problems ahead of the profession, and referred at some length to the coming changes in the Poor Law system.

A keen discussion followed the address, in which Drs. CANE, TAYLOR, BULMAN, WOODROFFE, and BOSWELL took part, special reference being made to the increasing inroads on private practice by the development of various health services under the control of local authorities. Dr. Cox having replied to the questions submitted, a very hearty vote of thanks was accorded to him on the proposal of Dr. EVANS, seconded by Dr. WOODROFFE. Dr. Cox briefly acknowledged the vote of thanks, saying that the discussion had been full of interest.

SURREY BRANCH: CROYDON DIVISION.

AN ordinary meeting of the Croydon Division was held at the Croydon General Hospital on January 25th, when Mr. E. M. COWELL, D.S.O., F.R.C.S., was in the chair. The Croydon section of the British Dental Association having received an invitation to attend, nineteen members of the dental profession were present.

A vote of condolence with the widow and family of the late Dr. Pasmore was passed, and the honorary secretary was instructed to convey it to Mrs. Pasmore.

Mr. E. M. Cowell and Dr. C. G. C. Scudamore were appointed the representatives in the Representative Body, and Dr. P. W. Hammond deputy representative.

Sir F. E. COLYER, K.B.E., gave an address on "Dental sepsis in relation to other pathological conditions," illustrated with lantern slides. In the subsequent discussion members of both Associations took part. Mr. A. B. ODDIE, chairman of the Dental Association, proposed a cordial vote of thanks to Sir Frank Colyer, which was carried with enthusiasm.

TANGANYIKA TERRITORY BRANCH.

A SCIENTIFIC meeting of the Tanganyika Territory Branch was held in the European Hospital, Dar-es-Salaam, on August 28th, 1926, when the President, Dr. PUGH, was in the chair.

Dr. C. F. SHELTON presented a memorandum relating to the revised scales of salaries recently introduced for the East African Medical Service, and pointed out that medical officers hereafter joining it were relatively worse off than officers of other departments. He added that to invite medical men to start on a lower scale was a retrograde move, and while admitting that medical officers already in the service had been generously treated, he thought that the newly joining medical officer was not being considered so well as he should be.

Dr. P. A. CLEARKIN agreed that medical officers had not received the same consideration as other officers. The young medical practitioner had had a long and expensive training; he entered the service later in life than most other officers, and had greater responsibilities at an earlier age; he was also likely to marry sooner. His expenses were no less than those of others, and yet administrative officers joining younger had greater chances of promotion, and proportionately a greater benefit from revised salaries. He mentioned that this was intended as a comment and not as a complaint; he agreed with Dr. Shelton that those already in the service had no grounds for complaint.

Dr. A. MCKENZIE had calculated the average age of entry into the various departments; the medical officers were the oldest in starting, their average age being 29.9 years, as compared with 24, which was the average age for cadets. He considered that the profession was being "cheapened."

Dr. J. PUGH (President) suggested that, before taking any other action, the Branch should invite the opinions of the other East African Branches, and this proposal was approved.

Dr. MCKENZIE read a paper entitled "An examination of the question of quinine prophylaxis," which gave excellent scope for discussion. A long debate followed in which all members took part.

Dr. BURKE-GAFFNEY (honorary secretary and treasurer) proposed that a full account of this and of all subsequent meetings should be forwarded to the *Kenya Medical Journal*. They were all anxious to see a united East African Medical Service, and the surest way of achieving it was to have some medium through which the various units of the service could combine. The *Kenya Medical Journal* was the only medical journal in East Africa, and provided an ideal medium for their purpose. He would like to see every member become, not only a regular subscriber, but also a regular contributor to it, and he hoped that in the future, through it, they would obtain an *East African Medical Journal* and a completely unified service. He urged every member to enrol at once as a subscriber to the *Journal*.

This proposal having been passed, the meeting adjourned.

A further scientific meeting of the Branch was held in the European Hospital, Dar-es-Salaam, on October 22nd, 1926, when the President, Dr. PUGH, was in the chair.

The President read extracts from a memorandum which had been recently received from the Uganda Branch, relating to the revised scales of salaries for the East African Medical Service. After some discussion it was resolved that a small subcommittee be appointed to go into the figures of the Uganda report, comparing them with the parallel figures in this territory, and that they make a report on their findings to the Branch Council. The procedure to be adopted with regard to the salaries question was left to the discretion of the Branch Council.

A subcommittee, consisting of Drs. Shelton and McKenzie, was accordingly appointed.

Dr. C. F. SHELTON, in a paper on "Amoebic abscess of the liver," discussed the subject of diagnosis and treatment from a practical standpoint. He illustrated his points with accounts of cases which had come within his own experience. A discussion followed in which all members took part, after which the PRESIDENT announced that the annual general meeting would be held on December 3rd, and the proceedings terminated.

YORKSHIRE BRANCH: WAKEFIELD, PONTEFRACT, AND CASTLEFORD DIVISION.

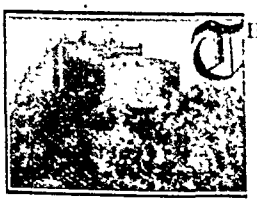
AT the meeting of the Wakefield, Pontefract, and Castleford Division held at Wakefield on January 13th, when the chairman, Dr. T. GIBSON, and twenty-one members were present, Dr. T. WARDROP GRIFFITH gave an extremely interesting lecture, which was much appreciated. He gave an account of irregular action of the heart from the general practitioner's point of view, and explained how the work of the pioneers of "instrumental" cardiac research had enabled the diagnosis of such conditions as auricular fibrillation to be made with reasonable accuracy without the aid of tracings. The following took part in the subsequent discussion: Drs. T. GIBSON, W. STEVEN, G. W. THOMAS, J. A. FULLERTON, T. E. LISTER, and N. S. TWIST.

British Medical Association.

NINETY-FIFTH ANNUAL MEETING, EDINBURGH, JULY, 1927.

Patron: HIS MAJESTY THE KING.

President: R. G. HOGARTH, C.B.E., F.R.C.S., Senior Surgeon, General Hospital, Nottingham.



President-Elect: SIR ROBERT W. PHILIP, M.D., LL.D., F.R.C.P.Ed., Consulting Physician, Royal Infirmary, Edinburgh.

Chairman of Representative Body: H. B. BRACKENBURY, M.R.C.S., L.R.C.P.

Chairman of Council: SIR ROBERT BOLAM, M.D., LL.D., F.R.C.P.

Treasurer: N. BISHOP HARMAN, M.B., F.R.C.S.

PROVISIONAL PROGRAMME.

Edinburgh Castle.

THE incoming President, Sir ROBERT PHILIP, will deliver his Address to the Association on Tuesday, July 19th, at 8 p.m.

The ANNUAL REPRESENTATIVE MEETING will begin on Friday, July 15th, at 10 a.m., and be continued on the three following week-days. The Representatives' Dinner will take place at the University Union on Friday evening, July 15th, at 7.30 p.m.

The statutory ANNUAL GENERAL MEETING will be held on Tuesday, July 19th, at 2 p.m., and the adjourned general meeting at 8 p.m.

The Annual Dinner of the Association will take place on Thursday, July 21st.

The Conference of Honorary Secretaries will be held at 2.30 p.m. on Wednesday, July 20th, and the Secretaries' Dinner at 6.30 the same evening.

The official Religious Service will be held in St. Giles's Cathedral on Tuesday, July 19th, at 4.30 p.m.

The Annual Exhibition of surgical appliances, foods, drugs, and books will be open for inspection on Monday, July 18th, from 2 till 6 p.m.; the formal opening by the President will take place on July 19th at 9.30 a.m. The exhibition will remain open on July 20th, 21st, and 22nd from 9 a.m. to 6 p.m.

A Centenary Celebration commemorative of the birth of Lord Lister, presided over by the Earl of Balfour, K.G., will take place on the evening of Wednesday, July 20th.

Saturday, July 23rd, will be given to excursions to places of interest in the neighbourhood.

THE SECTIONS.

The Scientific Sections will meet from 10 a.m. to 1 p.m. for papers and discussions on Wednesday, Thursday, and Friday, July 20th, 21st, and 22nd.

The following Sections will meet on Three Days.

MEDICINE.

President: Professor G. LOVELL GULLAND, C.M.G., M.D., F.R.C.P.Ed. (Edinburgh).

Vice-Presidents: J. HILL ABRAM, M.D., F.R.C.P. (Liverpool); R. A. FLEMING, M.D., F.R.C.P.Ed. (Edinburgh); H. MORLEY FLETCHER, M.D., F.R.C.P. (London); W. T. RITCHIE, O.B.E., M.D., F.R.C.P.Ed. (Edinburgh).

Honorary Secretaries: GEORGE GRAHAM, M.D., F.R.C.P., 1, Devonshire Place, London, W.1; G. D. MATHEWSON, M.B., F.R.C.P.Ed., 28A, Moray Place, Edinburgh.

SURGERY.

President: Professor D. P. D. WILKIE, O.B.E., M.D., Ch.M., F.R.C.S. (Edinburgh).

Vice-Presidents: J. W. DOWDEN, C.M., F.R.C.S.Ed. (Edinburgh); F. J. STEWARD, M.S., F.R.C.S. (London); J. W. STRUTHERS, F.R.C.S.Ed. (Edinburgh); H. WADE, C.M.G., D.S.O., F.R.C.S.Ed. (Edinburgh); A. M. WEBBER, M.S., F.R.C.S. (Nottingham).

Honorary Secretaries: J. M. GRAHAM, Ch.M., F.R.C.S.Ed., 8, Manor Place, Edinburgh; E. C. HUGHES, O.B.E., M.Ch., F.R.C.S., 17, Wimpole Street, London, W.1.

OBSTETRICS AND GYNAECOLOGY.

President: JAMES HAIG FERGUSON, M.D, C.M., F.R.C.P.Ed., F.R.C.S.Ed. (Edinburgh).

Vice-Presidents: T. WATTS EDEN, M.D., F.R.C.P., F.R.C.S.Ed. (London); GIBBON FITZGIBBON, M.D., F.R.C.P.I. (Dublin); WILLIAM FORDYCE, M.D., F.R.C.P.Ed. (Edinburgh); Professor R. W. JOHNSTONE, C.B.E., M.D., F.R.C.S.Ed. (Edinburgh); Mrs. ETHEL VAUGHAN-SAWYER, M.D. (London).

Honoraries Secretaries: DANIEL DOUGAL, *M.C.*, M.D., 11, St. John Street, Manchester; W. F. T. HAULTAIN, O.B.E., *M.C.*, M.B., Ch.B., F.R.C.S.Ed., 6, Walker Street, Edinburgh.

PATHOLOGY AND BACTERIOLOGY.

President: Professor J. LORRAIN SMITH, M.D., F.R.S., F.R.C.P.Ed. (Edinburgh).

Vice-Presidents: J. W. DAWSON, M.D., D.Sc., F.R.C.P.Ed. (Edinburgh); W. R. LOGAN, M.D., F.R.C.P.Ed. (Edinburgh); Professor T. J. MACKIE, M.D., D.P.H. (Edinburgh); H. D. WRIGHT, M.D., M.R.C.P.Ed. (London).

Honorary Secretaries: JAMES DAVIDSON, M.B., Ch.B., Pathological Department, University of Edinburgh; H. J. PARISH, M.D., D.P.H., Wellcome Physiological Research Laboratories, Langley Court, Beckenham, Kent.

THERAPEUTICS AND PHARMACOLOGY.

President: Professor J. A. GUNN, M.D., D.Sc. (Oxford).

Vice-Presidents: Professor A. J. CLARK, *M.C.*, M.D., F.R.C.P. (Edinburgh); Professor FRANCIS R. FRASER, M.D., F.R.C.P. (London); E. P. POULTON, M.D., F.R.C.P. (London).

Honorary Secretaries: E. G. HOLMES, M.B., B.Chir., Pharmacological Laboratory, Cambridge; C. G. LAMBIE, *M.C.*, M.B., F.R.C.P.Ed., 31, Drumsheugh Gardens, Edinburgh.

DISEASES OF CHILDREN.

President: Professor JOHN FRASER, *M.C.*, M.D., Ch.M., F.R.C.S.Ed. (Edinburgh).

Vice-Presidents: H. CHARLES CAMERON, M.D., F.R.C.P. (London); ALEXANDER DINGWALL FORDYCE, M.D., F.R.C.P.Ed. (Liverpool); CHARLES MCNEIL, M.D., F.R.C.P.Ed. (Edinburgh).

Honorary Secretaries: Miss HELEN M. M. MACKAY, M.D., 28, John Street, Bedford Row, London, W.C.1; LEWIS THATCHER, M.D., F.R.C.P.Ed., 8, Melville Crescent, Edinburgh.

MENTAL DISEASES.

President: Professor GEORGE M. ROBERTSON, M.D., F.R.C.P.Ed. (Edinburgh).

Vice-Presidents: BERNARD HART, M.D., F.R.C.P. (London); JOHN KEAY, C.B.E., M.D., F.R.C.P.Ed. (Bangour); J. R. LORD, C.B.E., M.D., F.R.C.P.Ed. (Epsom); H. C. MARR, M.D., F.R.F.P.S.Glas. (Edinburgh).

Honorary Secretaries: R. D. GILLESPIE, M.D., 152, Harley Street, London, W.1; W. M. MCALISTER, M.B., Ch.B., M.R.C.P.Ed., 151, Morningside Drive, Edinburgh.

The following Sections will meet on Two Days.

NEUROLOGY.

President: Professor EDWIN BRAMWELL, M.D., F.R.C.P. (Edinburgh).

Vice-Presidents: ALEX. NINIAN BRUCE, M.D., D.Sc., F.R.C.P.Ed. (Edinburgh); J. GODWIN GREENFIELD, M.D., F.R.C.P. (London); F. M. R. WALSHE, O.B.E., M.D., D.Sc., F.R.C.P. (London).

Honorary Secretaries: E. A. CARMICHAEL, M.B., Ch.B., F.R.C.P.Ed., National Hospital, Queen Square, London, W.C.1; NORMAN M. DOTT, M.B., F.R.C.S.Ed., 8, Grosvenor Crescent, Edinburgh.

OPHTHALMOLOGY.

President: A. H. H. SINCLAIR, M.D., F.R.C.S.Ed. (Edinburgh).

Vice-Presidents: WILFRED ALLPORT, M.B., F.R.C.S.Ed. (Birmingham); Sir ARNOLD LAWSON, K.B.E., F.R.C.S. (London); H. M. TRAQUAIR, M.D., F.R.C.S.Ed. (Edinburgh).

Honorary Secretaries: R. E. BICKERTON, D.S.O., M.B., Ch.B., 33, Portland Place, London, W.1; E. H. CAMERON, M.B., Ch.B., F.R.C.S.Ed., 7, Darnaway Street, Edinburgh.

LARYNGOLOGY AND OTOLOGY.

President: A. LOGAN TURNER, M.D., F.R.C.S.Ed. (Edinburgh).

Vice-Presidents: J. S. FRASER, M.B., F.R.C.S.Ed. (Edinburgh); W. M. MOLLISON, C.B.E., M.Chir., F.R.C.S. (London); DONALD R. PATERSON, M.D.Ed., F.R.C.P. (Cardiff).

Honorary Secretaries: A. R. DINGLEY, F.R.C.S., 47, Queen Anne Street, London, W.1; W. T. GARDINER, *M.C.*, M.B., Ch.B., F.R.C.S.Ed., 18, Chester Street, Edinburgh.

PREVENTIVE MEDICINE.

President: Professor P. S. LELEAN, C.B., C.M.G., F.R.C.S., D.P.H. (Edinburgh).

Vice-Presidents: G. F. BUCHAN, M.D., D.P.H. (London); Miss HARRIETTE CHICK, D.Sc. (London); A. M. HEWAT, M.D., D.P.H. (London); G. R. LEIGHTON, O.B.E., M.D., D.Sc. (Edinburgh).

Honorary Secretaries: W. T. BENSON, B.Sc., M.D., D.P.H., M.R.C.P.Ed., City Hospital, Comiston Road, Edinburgh; C. W. HUTT, M.D., D.P.H., Council Offices, 197, High Holborn, London, W.C.

PHYSIOLOGY AND BIOCHEMISTRY.

President: Professor Sir EDWARD SHARPEY-SCHAFER, M.D., LL.D., D.Sc., F.R.S. (Edinburgh).

Vice-Presidents: P. T. HERRING, M.D., F.R.C.P.Ed. (St. Andrews); Professor D. MURRAY LYON, M.D., D.Sc., F.R.C.P.Ed. (Edinburgh); Professor JOHN MELLANBY, M.D. (London); Professor T. H. MILROY, M.D. (Belfast); Professor JOHN TAIT, M.D., D.Sc. (Montreal).

Honorary Secretaries: Professor B. A. MCSWINEY, M.B., B.Ch., School of Medicine, Leeds; Miss MAY LAURIE WALKER, B.Sc., M.B., Ch.B., Department of Physiology, University of Edinburgh.

COMPARATIVE MEDICINE.

President: Principal O. C. BRADLEY, M.D., D.Sc., F.R.C.V.S. (Edinburgh).

Vice-Presidents: Professor J. B. BUXTON, M.A., F.R.C.V.S. (Cambridge); F. E. CREW, M.B., Ch.B. (Edinburgh); Major G. W. DUNKIN, M.R.C.V.S. (London).

Honorary Secretaries: T. W. M. CAMERON, Ph.D., B.Sc., M.R.C.V.S., London School of Hygiene and Tropical Medicine, 23, Endsleigh Gardens, London, W.C.1.; J. RUSSELL GREIG, M.R.C.V.S., Royal (Dick) Veterinary College, Edinburgh.

The following Sections will meet on One Day.

DERMATOLOGY.

President: ROBERT CRANSTON LOW, M.D., F.R.C.P.Ed. (Edinburgh).

Vice-Presidents: W. HERBERT BROWN, M.D. (Glasgow); H. D. HALDIN-DAVIS, M.D., F.R.C.S. (London).

Honorary Secretaries: ROBERT AITKEN, M.D., F.R.C.P.Ed., 8, Palmerston Place, Edinburgh; F. D. HOWITT, M.D., 87, Harley Street, London, W.1.

TROPICAL DISEASES.

President: ANDREW BALFOUR, C.B., C.M.G., M.D., F.R.C.P.Ed., D.P.H. (London).

Vice-Presidents: Lieut.-Colonel E. D. W. GREIG, C.I.E., M.D., D.Sc. [illegible] Colonel W. F. HARVEY, C.I.E., M.D., C.M., Lieut.-Colonel W. GLEN LISTON, C.I.E., M.D., D.P.H. (Edinburgh); Lieut.-Colonel W. P. MACARTHUR, D.S.O., O.B.E., M.D., F.R.C.P.I., D.P.H. (London).

Honorary Secretaries: A. R. D. ADAMS, M.B., Ch.B., D.T.M., School of Tropical Medicine, University of Liverpool; J. F. C. HASLAM, *M.C.*, M.B., D.P.H., Bureau of Hygiene and Tropical Diseases, 23, Endsleigh Gardens, London, W.C.1.

FORENSIC MEDICINE.

President: Professor H. HARVEY LITTLEJOHN, M.B., F.R.C.S.Ed. (Edinburgh).

Vice-Presidents: The Right Hon. Earl RUSSELL (London); Sir WALTER SCHRODER, K.B.E. (London); Professor SYDNEY A. SMITH, M.D., D.P.H. (Cairo).

Honorary Secretaries: D. J. A. KERR, M.B., Ch.B., D.P.H., M.R.C.P.Ed., Forensic Medicine Department, University, Teviot Place, Edinburgh; Professor J. E. W. MCFALL, M.D., D.P.H., 15, Green Lane, Stoneycroft, Liverpool.

TUBERCULOSIS.

President: Professor S. LYLE CUMMINS, C.B., C.M.G., M.D. LL.D. (Cardiff).

Vice-Presidents: WILLIAM BRAND, M.B., C.M. (London); S. VERE PEARSON, M.D. (Mundesley); ERNEST WATT, M.D., D.Sc., M.R.C.P.Ed. (Edinburgh).

Honorary Secretaries: J. C. SIMPSON, *M.C.*, M.B., Ch.B., D.P.H., Gracemount Farm, Liberton, Edinburgh; R. R. TRAIL, *M.C.*, M.D., King Edward VII Sanatorium, Midhurst.

VENEREAL DISEASES.

President: DAVID LEES, D.S.O., M.B., F.R.C.S.Ed. (Edinburgh).

Vice-Presidents: ARCHIBALD CAMBELL, M.B., Ch.B. (Portsmouth); Mrs. MARGARET ROBKE, M.B., Ch.B. (London); R. STOPFORD TAYLOR, D.S.O., M.B., F.R.C.S.Ed. (Liverpool).

Honorary Secretaries: F. C. DOBLE, M.R.C.S., L.R.C.P., 93A, Harley Street, London, W.1; Miss MARY FORBES LISTON, M.B., Ch.B., 33, Comely Bank, Edinburgh.

RADIOLOGY.

President: J. M. WOODBURN MORISON, M.D., C.M., D.M.R.E. (Edinburgh).

Vice-Presidents: M. R. J. HAYES, F.R.C.S.I. (Dublin); F. SHILLINGTON SCALES, M.D. (Cambridge).

Honorary Secretaries: W. CRICHTON FOTHERGILL, M.B., Ch.B., D.M.R.E., 5, Hermitage Drive, Edinburgh; JOHN MUIR, O.B.E., M.B., B.Ch., British Institute of Radiology, 32, Welbeck Street, London, W.1.

HISTORY OF MEDICINE.

President: JOHN D. COMRIE, M.D., F.R.C.P.Ed. (Edinburgh).

Vice-Presidents: ARNOLD CHAPLIN, M.D., F.R.C.P. (London); CHARLES SINGER, M.D., D.Litt., F.R.C.P. (London); R. W. INNES SMITH, M.D. (Sheffield); HENRY S. WELLCOME (Beckenham).

Honorary Secretaries: WALTER J. DILLING, M.B., Ch.B., Faculty of Medicine, University of Liverpool; ADAM CAIRNS WHITE, M.B., Ch.B.Ed., Pharmacological Department, University of Edinburgh.

MEDICAL SOCIOLOGY.

President: F. N. KAY MENZIES, M.D., F.R.C.P.Ed., D.P.H. (London).

Vice-Presidents: L. D. CRUICKSHANK, M.D., M.R.C.P.Ed., D.P.H. (Edinburgh); Sir HENRY S. KEITH, J.P. (Hamilton); the Hon. Lord MACKENZIE, LL.D. (Edinburgh); the Hon. Sir ARTHUR STANLEY, G.B.E., C.B., LL.D., Hon. F.R.C.P.Ed. (London); Sir NORMAN WALKER, M.D., LL.D., F.R.C.P.Ed. (Edinburgh).

Honorary Secretaries: T. YULE FINLAY, M.D., M.R.C.P.Ed., 9, Hermitage Gardens, Edinburgh; B. S. SIMMONDS, M.S., F.R.C.S., 124, Harley Street, London, W.1.

The Honorary Local General Secretary of the Annual Meeting is A. FERGUS HEWAT, M.D., F.R.C.P.Ed., 14, Chester Street, Edinburgh.

National Insurance.

DENTAL BENEFIT.

THE Ministry of Health, in a communication dated January 31*st*, states that approved societies under the National Health Insurance scheme are now spending a sum of over £2,000,000 a year on the provision of dental treatment as an additional benefit. In order to enable societies to obtain a second opinion as to the need for such treatment and to check estimates of cost received from dentists, and the standard of work and materials supplied, a service of regional dental officers is being set up by the Ministry. There are to be six full-time regional dental officers in England and Wales, who will be stationed at London (2), Birmingham, Manchester, Leeds, and Cardiff.

The following appointments have been made by the Minister of Health on the recommendation of a committee which has considered all applications received for the posts: Mr. H. A. Mahony (principal regional dental officer) and Mr. Arthur Taylor in London; Mr. J. Woodford-Williams in Cardiff; and Messrs. H. G. H. Cowell and T. Dilks Page. One other appointment has yet to be made. The cost of the service is to be met out of the funds of the approved societies providing dental benefit under the new arrangements which have been agreed upon between representatives of the societies and the dental profession.

LOCAL MEDICAL AND PANEL COMMITTEES.

NEWCASTLE-ON-TYNE.

Dinner to Dr. Brackenbury.

DR. H. B. BRACKENBURY, Chairman of the Representative Body, British Medical Association, was the guest of the Panel Committee of Newcastle-on-Tyne at dinner at the Station Hotel, Newcastle, on January 28th. Dr. G. ROY FORTUNE (Chairman of the Committee) presided over a large and influential gathering, which included Sir Thomas Oliver (President of the University of Durham College of Medicine), Sir Robert Bolam (Chairman of Council, British Medical Association), Mr. Charles Irwin, Councillor W. A. Allan, Dr. Farquhar Murray, Dr. Evers, Dr. Forbes (Secretary of the Gateshead Panel Committee), Dr. Harold Kerr (Medical Officer of Health for Newcastle), Mr. Samuel Phillips, Mr. John *Bell*, Dr. *Dickie* (Morpeth), and Mr. Stanley Worthington (Secretary).

After the loyal toast had been honoured, the CHAIRMAN gave "Our Guest." He said they were under many debts of *obligation* to Dr. Brackenbury. Apart from being a brilliant member of their profession, he had done a great work municipally and educationally. He was a man of vision, which was proved by the fact that while the profession was harping and carping about the Insurance Act he was making a study of it, and saw the great benefits which would accrue to the nation by the *adoption* of the Act. He believed in paying that tribute to Dr. Brackenbury, for very often people did not give honour where honour was due, and only when a man had gone to his rest did he get any praise. But "A word spoken when the hearts are broken is very poor comfort at best." The work he had done on behalf of the profession they greatly appreciated, and it was from a wish to help him on his way to further achievement that they were entertaining him that night.

Dr. Brackenbury's Speech.

The toast was given musical honours, and in the course of his reply Dr. BRACKENBURY thanked Dr. Fortune for the warmth and cordiality of his welcome. He assumed that the reason for the

invitation to him to be their guest was that he might be able to tell them something about one or two points which were important with regard to the administration of the National Insurance Act. It was a fact that there were certain medical practitioners who were very loath to learn the elementary facts about the Regulations and conditions under which they practised, and they still had letters in the BRITISH MEDICAL JOURNAL showing the complete ignorance of the most elementary facts about the insurance service, and he was tired of telling people over and over again those elementary facts. He did not propose to go over that ground again, because they were all well up in the matter, but there were two or three things which seemed to him to be important at the present time. The first thing was that, as members of a Panel Committee, they were charged primarily with the duty of looking after the peculiar interests of insurance practitioners in relation to that department of the Ministry of Health which administered the service at the centre. But he hoped they would never forget, and always act up to the remembrance of the fact, that they could not deal with one section of the profession in any way without more or less directly affecting the interests of the profession as a whole. The unity of the interests of the profession was becoming more and more evident. They could not raise the question of the remuneration of medical practitioners or medical officers without immediately affecting in some degree, perhaps in a great degree, the interests of other sections of the profession. That was true not only in regard to remuneration, but also in regard to conditions of service. It was astonishing to find how many people saw immediately how a certain thing was going to benefit a particular group without looking to see how adversely the establishment of such a practice would affect the interests of the profession when regarded as a whole. So that, in their work as members of a Panel Committee, it was of great importance, in making their arrangements with the Government department concerned and the Insurance Committees, to bear in mind how those particular arrangements were going to affect, not merely themselves and their colleagues in the immediate future, but also how they must establish principles which, as the service extended, would hold and be difficult to remove. They must always bear in mind that other people would have to serve under conditions which they, with their tendency to a narrower outlook, were instrumental in shaping.

Two things (Dr. Brackenbury continued) were exercising the minds of the Insurance Acts Committee and the Ministry of Health, and they were of very great importance. One was the extraordinary situation which had arisen with regard to sickness benefit during the past eight months—a situation which must have been of very great concern to a place like Newcastle and the north-east coast, where the effect of the coal strike and unemployment had been so great. That situation raised the question of the relation of doctors under the Insurance Act to the enormous increase in the claims for sickness benefit. The increase in some societies and in some places had been as much as 300 per cent., while at the same time, in some areas very indirectly affected by strike conditions, the claims had in fact diminished. It did not follow from that that there was any increase of wickedness on the part of the certifying doctor, but it did indicate a very natural attitude on the part of the profession, which, when looked at from a different point of view, did not seem to be quite the right thing. Of course, they as doctors had by training and tradition been brought into the attitude that when they had a patient before them they thought of doing nothing but the best they could for the patient; and anything they could do for the patient, whether it was strictly medical or not, they were anxious to do. They were apt to forget what he was bound to say they had to remember, even though it was against their traditional attitude, and that was that when they were dealing with insured persons they had to put themselves into the position of a lawyer, which was on the whole antagonistic to the medical man's attitude. They must say, "This is a definite insurance scheme. Certain premiums are being extracted from these persons, and what they are entitled to as a result of the premium is a certain specified and specific limited benefit." It might be that the State would have been wiser to have extracted larger premiums and given greater benefits, or less premiums and lesser benefits. But the lawyer's point of view was, "Here is a scheme for which a limited premium is being paid, and the benefits are limited—the benefits do not include everything that would benefit the patient. For that premium there is only bought this specific and limited sickness benefit which is defined in an Act of Parliament, and explained in Regulations and Memoranda of the Government department." The seriousness of the situation was this—that if it became evident that insurance practitioners as a whole were unable temperamentally, by tradition and training, to take themselves out of the natural medical attitude, which was to give the patients everything that could be given, not by any unworthy motive but in order to improve their well-being, then there might be all sorts of serious alternatives put up to them by administration and legislation which they would not like, and which would take out of their hands the function of certifying, and put that function into the hands of an independent and whole-time body of medical men, who would inevitably have larger and larger functions imposed upon them. They must remember that all that the insured person was entitled to was a certain specific benefit, otherwise very serious difficulties would arise. The accusation that this increase of sickness benefit had come about by lax and false certifying was not true. There was no evidence of it, but he could quite see how it might innocently and even in a praiseworthy fashion have arisen because of the natural attitude of a medical man to the patient he had before him. The other point about which they were concerned at the moment might be called the judicial procedure of the Ministry of Health—that was to say, the procedure in connexion with complaints that were made from time to time against medical men by approved societies or by dissatisfied patients, who, under the Insurance Act, had the statutory right to put forward their complaints in a particular way. For a long time they had been profoundly dissatisfied with some of the methods by which the inquiry into the complaints was being conducted, and there was also growing dissatisfaction about the encroachment of the Ministry of Health into the purely professional sphere, and by that he meant the actual relations of doctor and patient when once those relations had been established. What the State had given to the insured person was the right to secure for himself a doctor who would be in the relation of family doctor or private practitioner towards him, and when once the State had established that relationship the State had a very doubtful right to further control or interference. That was to say, that in their relations with their patients they did not easily tolerate the interference of a third party. They wanted that interference reduced to a minimum, and they also wanted, more than anything else, some knowledge of what went on when the complaint was passed from the Insurance Committee to the Ministry of Health, and before the Minister announced his decision upon the facts. If they were successful in securing a full knowledge of what happened, and also secured a small representative, independent, professional committee, who would consider and report before any decision was given, it would go a long way to satisfy them. In the absence of knowledge they were apt to be suspicious about some of the extraordinary decisions which had been given in recent years. He was hoping that both the matters upon which he had dwelt would soon be settled to their satisfaction. At all events, they were doing their best to see that they were taken up in a reasonable spirit.

What were the chances of the extension of the Insurance Act so as to provide a consultant and specialist service actually maturing? They all knew that that was a recommendation of the Royal Commission, and the profession was demanding that if there were to be any extensions that that should be the first extension which was entered upon. There were two very great difficulties in the way. In the first place, the Government had to persuade approved societies to agree to the pooling to a certain extent of the moneys which passed through their hands and were entered upon their books, and which they persistently claimed as being their money. As the law stood it required either highly controversial legislation, or agreement as the result of argument and persuasion, to get the approved societies to consent to a relatively small proportion of that money being pooled for this particular purpose. That was the first hedge that had to be got over, and it was not an easy task which the Government had to face. After that consent had been obtained, if it could be obtained, there would have to be legislation, and in these crowded sessions of Parliament it was not easy for a Ministry of Health, already occupying a great part of parliamentary time, to introduce even uncontroversial legislation for which there was no popular outcry. But that it would be secured in the not very distant future he thought there could be no doubt, and it might be that in two years or so they might find they had established for the benefit of the insured persons, and under conditions of advantage to the consultants themselves, that extension of the Insurance Act.

Dr. JAMES HUDSON proposed the toast of "The University of Durham College of Medicine," to which Sir THOMAS OLIVER responded.

The health of the Chairman was proposed by Sir ROBERT BOLAM, and it was given musical honours.

LONDON PANEL COMMITTEE.

A MEETING of the London Panel Committee was held on January 25th, Dr. H. J. CARDALE presiding. Dr. J. M. Bailey, Dr. L. G. Glover, and Dr. A. G. Newell were appointed members of the committee to fill vacancies.

Claims for Payment for Anaesthetist.—The CHAIRMAN stated that a deputation from the committee had recently approached the Ministry of Health to suggest certain amendments in the procedure concerning claims for payment for the services of an anaesthetist. The Ministry was unable to accept the alteration suggested by the committee, but pointed out that the object could be effected under the present distribution scheme inasmuch as it was open to the committee to disallow a claim for a guinea for the administration of chloroform or ether if, after due investigation of the facts of the case, the committee was satisfied that the operation was of such a nature that it could properly have

been performed under nitrous oxide gas. Such disallowances had in fact been made by other Panel Committees. The Chairman said that this suggestion of the Ministry must be interpreted to mean that the committee was at liberty to disallow a claim for a guinea in such cases and to allow a fee of half a guinea. It was agreed to take no further action on the proposed amendment, but that the committee should exercise its discretion under this clause in dealing with claims for the payment of a fee for the services of a second practitioner in administering a general anaesthetic.

The Medical Service Subcommittee.—It was agreed to ask the medical representatives upon the Medical Service Subcommittee to furnish the reasons advanced by that subcommittee when exercising its discretion in hearing cases of complaint against practitioners where the period of six weeks allowed by the regulations for the lodging of complaints had expired. It was stated that the subcommittee had even proposed to hear one complaint although two and a half years had elapsed since the incident occurred. This, however, had fallen through owing to withdrawal by the complainant.

Public Medical Service.—A meeting of the Central Committee of Management of the Public Medical Service for London followed the meeting of the Panel Committee. It was stated that this would be the last meeting of the temporary committee, which would give place to a permanent committee at the first annual meeting of the Service shortly to be held. The number of subscribers was now 5,361. In response to a vote of thanks, Dr. E. A. GREGG said that he thought the institution of the Public Medical Service was one of the most useful things which had ever been done in conjunction with the work of the Panel Committee. His only regret was that the profession in general had been so apathetic in backing those who had blazed the trail. The Service was shaping well, but its strength ought to be about double what it was. There were some practitioners who apparently expected that the Service would do their business for them, simply handing them a long list of patients and a handsome cheque every month. Probably when the venture had proved an assured success they would wake up to its advantages.

BIRMINGHAM.

AT a meeting of the Birmingham Panel Committee on December 21st, 1926, Dr. H. G. DAIN, who took the chair, gave an account of the Conference of Local Medical and Panel Committees in October. The matters with which the Conference was chiefly concerned were the alteration of the disciplinary machinery and the great increase in sickness benefit claims, both of which were referred to the Insurance Acts Committee for consideration and discussion with the Ministry. Dr. W. J. GARRUTT reported his success in interviewing doctors who had claimed emergency fees for seeing their neighbours' patients, and in getting the claims withdrawn. This seemed to be a move in the right direction, and would promote more friendliness.

Prolonged discussion followed a resolution, moved by Dr. BURGES, that the Panel Committee disapproved of the recommendation of the Royal Commission that Insurance Committees should be abolished and their duties placed upon county or county borough councils. It was pointed out that the doctors had now an established position with Insurance Committees, and were working harmoniously with them; that it might, and probably would, be difficult to establish similar relations with the local authorities; and that the unification of National Health Insurance with other health services under the control of the medical officer of health might prove to be a step in the direction of a whole-time service. The resolution was carried unanimously, and the Secretary was instructed to send it to the Ministry of Health, the Insurance Acts Committee, and the Birmingham Insurance Committee.

A letter was read from the Insurance Acts Committee with regard to the increase in sickness benefit claims, and it was decided that it be sent to every panel doctor in the area. Ward secretaries were asked to bring the matter up for discussion in their wards.

A development in the health lecture scheme was considered (and, with one dissentient, the Panel Committee agreed for a trial to be made) that where a doctor did not wish to lecture to his own patients, but was willing that some colleague from another part of the city, and of his own choice, should speak to his patients, such lectures might be arranged. The doctor would take the chair or otherwise associate himself with the lecture and lecturer. Considerable divergence of opinion on this question was expressed, but the feeling prevailed that it was in everybody's interest—patient, doctor, and Insurance Committee—that the panel doctor should be increasingly concerned in the prevention of illness, and that this suggestion should have a trial.

WARWICKSHIRE.

THE Warwickshire Local Medical and Panel Committee's bi-monthly meeting was held at Leamington on January 27th, Dr. HERBERT MALINS (Warwick) presiding.

Difficulties in the matter of tendering suitable advice as to economy in prescribing arose upon questions involving the use of radium derivatives and of organotherapy. In one case the propriety of an insurance practitioner's ordering of radium derivatives in his treatment of rodent ulcer was considered. It was generally understood that appropriate doses for administration would fall within the category of vaccines and form a legitimate charge on the Drug Fund; the practitioner being allowed to procure the material and submit a quarterly account in accordance with the local distribution scheme. On the other hand, the Committee held that the direct use of radium would not come within the scope of medical benefit, and that no question as to the cost of hiring radium should be entertained. Dealing with an inquiry as to an expensive proprietary pluriglandular extract which, while apparently proving highly beneficial, seemed to entail an indefinitely continuous charge on the Drug Fund, the feeling of members as expressed was that the practitioner would be required to prove that alternative glandular preparations, and combinations of them, at considerably less cost were not efficacious in a particular case.

Extended consideration was given to the recent circular from the Medical Secretary on the subject of excessive sickness benefit claims. The views of several practitioners from mining areas such as Nuneaton, Atherstone, and Coventry districts were unanimous in praise of the attitude of the miners in relation to "going on the box." Suggestions that, so far as concerned the Warwickshire area, there had been [illegible] respectively by practitioners and workers were strongly repudiated; more than one specifically that in numbers of cases under his personal observation miners had refused to consider requesting medical certificates where such requests might reasonably have been made, advancing the view that their mates would hold them in contempt for such a proceeding. Unnecessary visitation during the "strike" had not been evidenced. At the same time there was a great deal of underfeeding. The Committee adopted the view that whilst there might have been a large increase in certification during the industrial dispute of last year, no data were forthcoming—only that relating to a South Wales area having apparently been adduced. The chairman said that it was useless for any side to proceed by innuendo, and upon definite charges of slackness being raised they in Warwickshire would know what to do. At the same time every representative would continue to impress upon his constituents the need for strictest observance of the spirit of the certification rules.

LONDON INSURANCE COMMITTEE.

Disciplinary Cases and the Ministry of Health.

AT the meeting of the London Insurance Committee on January 27th a long and animated discussion took place on a suggestion by the Ministry of Health that a fine be inflicted on a practitioner with regard to whom the Medical Service Subcommittee had recommended only that he be cautioned.

Mr. H. H. MILLS, chairman of the subcommittee, said that this was a case in which the complaint against the practitioner was that he had refused to attend and provide treatment for an insured person since deceased. The case was considered at great length by the subcommittee last summer, and the unanimous conclusion, subsequently endorsed by the full committee, was that in the circumstances it was sufficient if the practitioner be cautioned. The Ministry had now written to say that, following upon an inquiry by its officers, it appeared that this was a case in which a fine ought to be imposed, and to ask the committee for any observations. Mr. Mills pointed out that on the finding of the committee, which contained only a caution, the practitioner had not appealed, but obviously he might have done so had the report recommended a monetary penalty; as it was he had allowed his right of appeal to go by. Mr. Mills urged that the matter be left where it was, and that the Ministry take the responsibility for any further steps. If it had not been for the energy of the subcommittee in pursuing the matter to a hearing it would have been dropped by the complainant, and he thought the careful attention which the subcommittee had given to the matter was entitled to respect.

It was proposed that the committee pass a resolution adhering to its original decision, but Mr. H. LESSER thought that something should be added to the effect that "having regard to its usual practice the committee requests that the question of withholding a part of the grant be determined by the Ministry of Health"—an addendum which led Dr. CARDALE to exclaim, "Willing to wound, and yet afraid to strike." Mr. SKINNER urged that after the time the committee had given to this case it was late in the day to ask it to revise its decision, especially in the direction of imposing a penalty.

Eventually a resolution by Mr. MILLS was agreed to, twenty voting in favour and none against, "That the committee adhere to its former decision and does not deem it equitable or just to make any recommendation as to the withholding of any portion of the grant."

In another case the Medical Service Subcommittee reported that on an appeal made by the practitioner against the decision of the committee it transpired that that decision had been founded on an inaccurate statement made by the witness who appeared on behalf of the insured person. The appeal was therefore allowed, and the Minister ordered the committee to pay a sum of five guineas towards the costs of the practitioner. A further letter had now been received from the Ministry stating that the Minister had had under consideration representations made to him by the Insurance Acts Committee that, having regard to the circumstances of the case, the practitioner was entitled to be reimbursed the whole of the costs incurred by him in pursuing his appeal. The Minister, therefore, had decided that the practitioner should be allowed his taxed costs, which amounted to 25 guineas, and requested the committee to pay to the practitioner, in addition to the 5 guineas already paid, a further sum of 20 guineas. The Ministry added that a grant of a corresponding amount would be made to the committee under the provisions of the appropriate article of the regulations.

In a case in which the committee had decided to censure a practitioner severely for negligence in failing to respond with reasonable promptness to a request made for his services, and had drawn the attention of the Minister to the case with a view

to a fine, which it suggested should be substantial, it was reported that the Minister, after taking into consideration the representations made by the practitioner to an officer of the Ministry, had decided to withhold the sum of £25 owing to the failure of the practitioner to comply with the terms of service.

During 1926 the practitioners' fund for London (amounting to £754,615) was debited by the Ministry with £197, representing sums withheld by the Minister from the money available for defraying the cost of medical benefit which would otherwise have been payable to the committee, owing to the default of certain practitioners. The drug fund for 1926 (amounting to £220,000) was similarly debited with £20, representing sums withheld owing to the default of certain chemists.

ANOTHER instance of a medical man being chosen by his medical and lay colleagues as chairman of an Insurance Committee is furnished by Dr. Thomas A. B. Soden, J.P., who was unanimously elected chairman of the Coventry Insurance Committee early last year.

Naval and Military Appointments.

ROYAL NAVAL MEDICAL SERVICE.

Surgeon Commanders L. O. Hunt and A. I. Sheldon are placed on the retired list with the rank of Surgeon Captain.

Surgeon Commanders H. R. B. Hull and T. J. D. Twigg to the *Egmont* for the *Maine*; F. G. Hitch to the *Victory* for Haslar Hospital; W. J. Morris to the *Marshal Soult*; G. Carlisle appointment to the *Victory* for Haslar Hospital cancelled.

Surgeon Lieutenant Commanders H. Hurst and E. B. Kelley to the *Tamar* additional and for R.N. Hospital, Hong-Kong.

Surgeon Lieutenants E. J. K. Weeks to the *Columbine* for Port Edgar Base; J. J. Mason to the *Argus*.

ROYAL NAVAL VOLUNTEER RESERVE.

Surgeon Commander J. H. G. Howe is placed on the retired list with the rank of Surgeon Captain.

Surgeon Lieutenant W. F. W. Bateson promoted to Surgeon Lieutenant Commander.

Surgeon Sublieutenants promoted to Surgeon Lieutenants: R. R. Dodd, R. Russell, and H. O'Connor.

Mr. H. P. Widdup has entered as Probationary Surgeon Lieutenant and attached to the London Division.

ROYAL ARMY MEDICAL CORPS.

The following Majors retire on retired pay: F. H. M. Chapman; J. L. Wood, O.B.E., and is granted the rank of Lieutenant-Colonel; J. H. Gurley, O.B.E.; H. W. Farebrother, and is granted the rank of Lieutenant-Colonel.

The following Captains to be Majors: H. C. Sandiford, M.C., W. D. Anderton, M.C., C. M. Foster (prov.), H. R. Sheppard (prov.), and D. W. Beamish, M.C. (prov.).

Captain D. W. M. Mackenzie is restored to the establishment.

Captain A. Rodd is placed on the half-pay list on account of ill health.

Captain M. St.C. Hamilton, half-pay list, late R.A.M.C., retires on account of ill health, receiving a gratuity.

ROYAL AIR FORCE MEDICAL SERVICE.

Flight Lieutenants J. A. Perdrau to Station Headquarters, Spittlegate; (Honorary Squadron Leader) C. A. Meaden to R.A.F. Station, Duxford; B. L. C. Fisher to Station Headquarters, Kenley; F. W. G. Smith to Headquarters, Air Defence of Great Britain, Uxbridge.

The following Flying Officers are promoted to the rank of Flight Lieutenant: C. G. J. Nicolls and B. Pollard.

Flying Officers E. J. Jenkins to No. 47 Squadron, Egypt; P. H. Perkins to R.A.F. Station, Worthy Down.

The seniority of Flying Officer E. Thompson as a Flying Officer is antedated to November 22nd, 1925.

INDIAN MEDICAL SERVICE.

Colonel A. A. Gibbs, K.H.P., to be Major-General, vice Major-General W. H. Ogilvie, C.B., C.M.G., K.H.P., appointed Director of Medical Services in India.

Lieut.-Colonel T. C. McCombie Young is placed on foreign service under the Indian Research Fund Association.

Lieut.-Colonel G. Tate, V.H.S., to be Colonel, vice Colonel A. W. R. Cochrane.

Lieut.-Colonel H. M. Brown has retired.

Captains to be Majors: B. Prasad, J. M. Mitchell, O.B.E., C. M. Ganapathy, M.C., and N. J. Gai.

Captain L. K. Ledger, an officiating Agency Surgeon, is posted as Medical Officer and ex-officio Vice-Consul, Sistan.

The promotion of Major F. Griffith is antedated from September 8th, 1926, to March 8th, 1926.

REGULAR ARMY RESERVE OF OFFICERS.

ROYAL ARMY MEDICAL CORPS.

Major T. A. Stephens, D.S.O., having attained the age limit of liability to recall, ceases to belong to the Reserve of Officers.

TERRITORIAL ARMY.

ROYAL ARMY MEDICAL CORPS

Lieut.-Colonel H. G. L. Haynes, from T.A. Reserve of Officers, to be Captain, with precedence as from October 25th, 1917, and relinquishes the rank of Lieutenant-Colonel.

A. H. Whyte to be Lieutenant.

TERRITORIAL ARMY RESERVE OF OFFICERS.

ROYAL ARMY MEDICAL CORPS.

Captain E. Coplans, from the active list; to be Captain.

COLONIAL MEDICAL SERVICES.

Dr. W. J. Hutchinson appointed Medical Officer, Kenya. Dr. G. J. Pirie appointed Deputy Director of Sanitary Service, Nigeria (retransferred from Gold Coast). Dr. F. McKernan appointed Medical Officer, Medical Department, Gold Coast. Dr. P. D. Oakley promoted Senior Medical Officer, Medical Department, Gold Coast. Dr. H. C. Hopkinson, Medical Officer, Nigeria, has resigned his appointment. Dr. W. M. Wade, Senior Medical Officer, Medical Department, Gold Coast, has retired on pension. Dr. C. L. Ievers, Senior Medical Officer, Tanganyika, transferred from Tanga to Dar-es-Salaam.

VACANCIES.

BIRMINGHAM AND MIDLAND EAR AND THROAT HOSPITAL.—Third House-Surgeon (non-resident). Salary £200 per annum.

BRISTOL EYE HOSPITAL.—House-Surgeon. Salary £150 per annum.

BURY AND DISTRICT JOINT HOSPITAL BOARD.—Resident Assistant to the Medical Superintendent. Salary £400 per annum, rising to £450.

CENTRAL LONDON THROAT, NOSE AND EAR HOSPITAL, Gray's Inn Road, W.C.1.—Resident House-Surgeon (male). Remuneration at the rate of £75 per annum.

DERBYSHIRE EDUCATION COMMITTEE.—School Dentist. Salary £500 to £550 per annum.

EAST LONDON HOSPITAL FOR CHILDREN, Shadwell, E.1.—(1) Surgeon. (2) Assistant Surgeon to see Out-patients.

GLOUCESTERSHIRE ROYAL INFIRMARY AND EYE INSTITUTION, Gloucester.—(1) House-Physician. (2) Assistant House-Surgeons. Males. Salary £150 and £120 per annum respectively.

HOSPITAL FOR SICK CHILDREN, Great Ormond Street, W.C.1.—Casualty Officer. Salary £400 per annum.

KENSINGTON, FULHAM, AND CHELSEA GENERAL HOSPITAL, Richmond Road, Earl's Court, S.W.5.—Senior and Junior Resident Medical Officers. Salary at the rate of £125 and £100 per annum respectively.

KING'S COLLEGE HOSPITAL, Denmark Hill, S.E.5.—Junior Physician for Diseases of the Skin.

MANCHESTER: ANCOATS HOSPITAL.—Assistant Surgical Registrar. Salary at the rate of £40 per annum.

MANCHESTER: ST. MARY'S HOSPITALS.—Resident Surgical Officer for the Whitworth Park Hospital. Salary £200 per annum.

NEW ZEALAND GOVERNMENT.—Senior Assistant Medical Officers in the Mental Hospitals Department. Salary £640 (single men), £775 (married).

ORKNEY, ISLAND OF SANDAY.—Medical Officer and Public Vaccinator. Salary £150.

QUEEN'S HOSPITAL FOR CHILDREN, Hackney Road, E.2.—(1) House-Physician and House-Surgeon; salary at the rate of £100 per annum. (2) Resident Medical Officer; salary, inclusive of panel fees, £200 per annum.

ROYAL FREE HOSPITAL, Gray's Inn Road, W.C.1.—(1) Assistant Physician. (2) Second Assistant in the Female Venereal Diseases Department; remuneration £1 1s. per session.

ROYAL LIVERPOOL CHILDREN'S HOSPITAL.—(1) Two Resident House-Physicians and two Resident House-Surgeons at the City Branch; salary at the rate of £60 per annum each. (2) Resident Medical Officer at the Heswall Branch; salary at the rate of £150 per annum.

ROYAL NORTHERN HOSPITAL, Holloway, N.—(1) Resident Medical Officer; salary £200 per annum, *plus* allowance for work in connexion with National Insurance Act. (2) House-Surgeon; salary at the rate of £70 per annum.

RYDE: CHILDREN'S HOSPITAL AND MATERNITY HOME.—Resident Medical Officer (unmarried). Salary at the rate of £100 per annum.

SCOTTISH BOARD OF HEALTH.—District Medical Officer. Remuneration £1,000 per annum, rising to £1,200.

SHEFFIELD ROYAL HOSPITAL.—Aural Surgeon.

STOKE-ON-TRENT: NORTH STAFFORDSHIRE ROYAL INFIRMARY.—Radiologist. Salary £500 per annum.

SUDAN GOVERNMENT: WELLCOME TROPICAL RESEARCH LABORATORIES, Khartoum.—Assistant Bacteriologist (unmarried). Salary £550 or £720, according to age and qualification, rising to £1,080, and thence to £1,200.

TYRONE COUNTY HOSPITAL, Omagh.—Lady Radiologist. Salary £75 per annum.

UNIVERSITY COLLEGE HOSPITAL, Gower Street, W.C.1.—(1) Associate Physician and Associate Surgeon on the Honorary Staff. (2) Registrar at the Royal Ear Hospital, Huntley Street, W.C.; honorarium, £50 per annum.

WHITEHAVEN AND WEST CUMBERLAND HOSPITAL.—Junior House-Surgeon (male). Salary £100 per annum.

WILLESDEN URBAN DISTRICT COUNCIL.—Assistant Medical Officer (male). Salary £600 per annum, rising to £750.

CERTIFYING FACTORY SURGEONS.—The following vacant appointments are announced: Stewarton (Ayr), Bilston (Stafford), Godalming (Surrey), Presteign (Radnor), Silsden (Yorkshire), Williton (Somerset). Applications to the Chief Inspector of Factories, Home Office, Whitehall, S.W.1.

This list of vacancies is compiled from our advertisement columns, where full particulars will be found. To ensure notice in this column advertisements must be received not later than the first post on Tuesday morning.

APPOINTMENTS.

BROCKBANK, William, M.A., B.Chir.Camb., M.R.C.P., Resident Medical Officer, Manchester Royal Infirmary.

BURT-WHITE, Harold, F.R.C.S., Honorary Obstetric Surgeon to the London Female Lock Hospital, Harrow Road, London, W.9.

GILMOUR, Charles, M.B., Ch.B.Glas., Resident Medical Officer, Grampian Sanatorium, Kingussie, N.B.

HEWER, C. Langton, M.B., B.S.Lond., a member of the Honorary Medical Staff, Queen's Hospital for Children, Hackney Road, E.2.

MACPIE, James D., M.B., Ch.B.Glas., Senior Resident Medical Officer, Winsley Sanatorium, near Bath.

VLASTO, M., M.B., F.R.C.S., Surgeon to the Ear, Nose, and Throat Department of the West London Hospital.

CERTIFYING FACTORY SURGEONS.—E. H. Milner, M.B., Ch.B.Leeds, for the Driffield District, Yorkshire; J. M. Wrangham, M.B., B.Chir.Camb., for the Ripponden District, Yorkshire.

DIARY OF SOCIETIES AND LECTURES.

ROYAL SOCIETY OF MEDICINE.

Section of [illegible] Pharmacology.—Tues., 5 p.m., Dr. J. W. Trevan [illegible] and Pharmacological Action. Other papers [illegible]

Section of Psychiatry.—Tues., 8.30 p.m., Drs. T. A. Ross and R. D. Gillespie: Progression and Regress[illegible]

Section of Surgery: Subsection of P[illegible]: [illegible] Gordon-Watson, Dr. Bertram Shires. The [illegible] by Dr. T. de Martel (Paris) and others.

Section of Neurology.—Thurs., 8.30 p.m., Dr. Arnold Carmichael: Optic Nystagmus.

Clinical Section.—Frl., 5 p.m., Cases.

Sections of Ophthalmology and Neurology.—Frl., 8.30 p.m., Special Discussion: The Value of Recent Methods of Treatment in the Late Stages of Ocular Syphilis; to be opened by Mr. J. H. Fisher and Dr. J. P. Martin, followed by Sir Arnold Lawson, Dr. A. Felling, and Mr. S. H. Browning.

BIOCHEMICAL SOCIETY.—At the Lister Institute of Preventive Medicine, Chelsea Bridge Road, S.W.1: Mon., 5 p.m., Communications:—(i) C. Dorée and E. C. Barton-Wright: A New Type of Alkali Lignin; (ii) F. Dickens, E. C. Dodds, W. Lawson, and N. F. Maclagan: Purification and Properties of Insulin; (iii) P. and M. G. Eggleton: Phosphoric Acid in Muscular Contraction; (iv) I. S. MacLean and C. G. Daubney: Lipins of Yeast; (v) W. T. J. Morgan: Methylated Derivatives of Hexosephosphoric Acids; (vi) A. Harden: Meyerhof's Theory of Alcoholic Fermentation; (vii) L. F. Hewitt: Proteins of the Cerebro-spinal Fluid; (viii) M. H. Roscoe: Nitrogen Metabolism Technique; (ix) H. W. Southgate: Gas Scrubber; (x) O. Rosenheim and T. A. Webster: Provitamin D; (xi) J. R. Marrack: Osmotic Pressure of Serum Proteins. Exhibits will be shown from 3.30 to 4.30 p.m.

MEDICAL SOCIETY OF LONDON, 11, Chandos Street, W.1.—Mon., 8.30 p.m., Discussion: Poliomyelitis; to be introduced by Dr. F. M. R. Walshe and Professor J. McIntosh, followed by Sir Thomas Horder.

WEST KENT MEDICO-CHIRURGICAL SOCIETY, Miller General Hospital, Greenwich, S.E.10.—Fri., 8.45 p.m., Address by Mr. Zachary Cope: Surgical Emergencies in General Practice.

POST-GRADUATE COURSES AND LECTURES.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION, 1, Wimpole Street, W.1.—Special Lecture at the Medical Society, 11, Chandos Street, W., Thurs., 5 p.m., Exanthemata, with Special Reference to Smallpox. Open to all members of the medical profession without fee. *Royal National Orthopaedic Hospital*, Great Portland Street, W.: Special Demonstration on Thurs., 3 p.m., open to all members of the medical profession without fee. *Paddington Green Hospital* and *Victoria Hospital*: Combined Course in Children's Diseases. All-day course. *St. John's Hospital*, Leicester Square, W.C.2: Special Course in Dermatology. Daily instruction in Out-patient Department. Lectures twice weekly. *London Lock Hospital*, Dean Street, W.: Special Course in Venereal Diseases. Afternoon and evening clinics daily with formal lectures. *National Hospital*, Queen Square, W.C.: Special Course in Neurology. Daily instruction and special lectures. All information as to fees, etc., obtainable from the Fellowship of Medicine, 1, Wimpole Street, W.1.

HOSPITAL FOR SICK CHILDREN, Great Ormond Street, W.C.1.—Thurs., 4 p.m., Care and Feeding of the Premature Infant.

LONDON SCHOOL OF DERMATOLOGY, St. John's Hospital, Leicester Square, W.C.2.—Tues., 5 p.m., Lichen Planus. Thurs., 5 p.m., Lupus Erythematosus.

NATIONAL HOSPITAL, Queen Square, W.C.1.—Mon., Tues., Thurs., Fri., 2 p.m., Out-patient Clinics. Mon., 12 noon, Pathology of the Nervous System; 3.30 p.m., Mental Sequelae of Encephalitis Lethargica. Tues., 3.30 p.m., Syphilis as it Affects the Nervous System. Thurs., 3.30 p.m., Poliomyelitis. Fri., 12 noon, Anatomy and Physiology of the Nervous System; 3.30 p.m., Demonstration of Re-education Methods.

NORTH-EAST LONDON POST-GRADUATE COLLEGE, Prince of Wales's General Hospital, Tottenham, N.15.—Mon., 10 a.m., Surgical Clinic; 2.30 to 5 p.m., Medical, Surgical, a[illegible]ics; Operations. Tues., 2.30 to 5 p.m., Medical, [illegible]nd Ear Clinics; Operations. Wed., 2.30 to 5 p.m. [illegible] Clinics; Operations. Thurs., 11.30 a.m., Dental Clinics; 2.30 to 5 p.m., Medical, Surgical, and Ear, Nose, and Throat Clinics; Operations. Fri., 10.30 a.m., Throat, Nose, and Ear Clinics; 2.30 to 5 p.m., Surgical, Medical, and Children's Diseases Clinics; Operations.

POST-GRADUATE HOSTEL, Imperial Hotel, Russell Square, W.C.1.—Mon., 9 p.m., Prostatic Disease. Thurs., 9 p.m., The Medical Witness in Relation to Crime.

ROYAL NORTHERN HOSPITAL, Holloway Road, N.—Tues., 3.15 p.m., Lecture Demonstration on Fractures.

TAVISTOCK CLINIC FOR FUNCTIONAL NERVE CASES, 51, Tavistock Square, W.C.1.—Mon. and Tues., 4.15 p.m., The Endocrines. Mon., Tues., and Wed., 5.15 p.m., Freud, Jung, and Adler from the Standpoint of Interrelation. Wed., 4.45 p.m., Psychotherapy. Thurs., 4.45 p.m., Treatment; 5.45 p.m., Adaptation. Fri., 4.45 p.m., Laboratory Tests for Disordered Function; 5.45 pm., Emotional Development.

WEST LONDON HOSPITAL POST-GRADUATE COLLEGE, Hammersmith, W.6.—Mon., 10 a.m. to 1 p.m., Genito-urinary Operations, Skin Department, Demonstration of Fractures; 2 p.m., Surgical Wards, Gynaecological and Eye Departments. Tues., 10 a.m. to 1 p.m., Lecture on Clinical Methods, Demonstrations in Venereal Diseases and Chest Cases; 2 p.m., Medical Wards, Throat, Nose, and Ear Department. Wed., 10 a.m. to 1 p.m., Children's Medical Out-patients, Medical Wards, Demonstration in Medical Pathology; 2 p.m., Surgical Wards, Eye Department. Thurs., 10 a.m. to 12 noon, Neurological Department; 2 p.m., Eye and Genito-urinary Departments, Gynaecological Ward. Fri., 10 a.m. to 1 p.m., Gynaecological Operations, Dental, Skin, and Electrical Departments; 2 p.m., Throat, Nose, and Ear Department. Sat., 10 a.m. to 1 p.m., Bacterial Therapy Department, Children's Medical Department. Daily: Operations, Medical and Surgical Out-patients at 2 p.m.

GLASGOW POST-GRADUATE MEDICAL ASSOCIATION.—At Royal Maternity and Women's Hospital. Wed., 4.15 p.m., Obstetrical Cases.

JAMES MACKENZIE INSTITUTE FOR CLINICAL RESEARCH, St. Andrews.—Tues., 4 p.m., Spitting of Blood.

SHEFFIELD UNIVERSITY POST-GRADUATE CLINICS.—At Royal Hospital: Fri., 3.30 p.m., Clinical Cases.

British Medical Association.

CURRENT NOTES.

Edinburgh Meeting: Section of Medical Sociology.

THE names of the officers of this Section were given in the list which appeared in the SUPPLEMENT last week. The personnel has, it will be noted, a strong bearing on the subject chosen for discussion: "The future relationship of the municipalities to the voluntary hospitals of this country." It is believed that the subject is particularly topical in view of the proposed reform of the Poor Law system, and those who wish to take part in the discussion should communicate with one of the Secretaries of the Section.

The Royal Army Medical Corps

There appears still to be in the minds of some a misconception as to the attitude of the British Medical Association in regard to the Royal Army Medical Corps, and this may be preventing suitable candidates from applying for commissions in that corps. It should be clearly understood that any differences of opinion there were between the Association and the War Office as regards the terms of service in the R.A.M.C. have been cleared up; that the Association is of opinion that the corps now offers a good career to suitable men; and that the Association is pledged to do whatever it can to induce young medical men of the right type to apply for commissions. Candidates should apply either to the dean of their medical school or direct to the Director-General, Army Medical Service, at the War Office, Whitehall, London, S.W.1.

Some Work of the Week.

The committee work of the week ending on February 5th illustrates the manner in which the British Medical Association seeks to meet the increasing demands upon its machinery and to extend its range of service both to the profession and to the public. The Standing Subcommittee of the Ethical Committee had under consideration on February 1st questions raised by the Federal Committee of the Association in Australia as regards the provision for confidential communications to members in connexion with ethical cases and some points in connexion with certain classes of advertisement in the JOURNAL which seem to call for a fresh definition of policy by the Council of the Association. It also embarked on a review of the central machinery for dealing with professional disputes, a topic referred to the Central Ethical and Medico-Political Committees by the Council in December, on consideration of a motion from the Metropolitan Counties Branch calling for a report on the subject to be presented to the Annual Representative Meeting. The Joint Subcommittee of the Science Committee and the Insurance Acts Committee on Collective Medical Research, whose first meeting was recorded in this column a fortnight ago, met again on February 2nd and continued to explore its field of reference. In formulating its proposals the subcommittee is making full use of the wide experience of the Association in the conduct of such research, in which notable pioneer work was done under the auspices of the Collective Investigation Committee of the Association between 1880 and 1890. A meeting with representatives of the Ministry of Health took place as arranged, the object being to secure such support in this work as may be rendered to the Association by the standing organization of the Ministry. Progress has been made with a scheme of no small potential value to the profession, and more particularly to general practitioners. A special subcommittee of the Public Health Committee, the fruit of a resolution of the Representative Body at Nottingham instructing the Council to consider and report on how Branches and Divisions of the Association, as voluntary bodies, can make a contribution towards public education in health as advocated in Sir George Newman's memorandum, held its second meeting; its reference had been extended by the Council to a consideration of "How the British Medical Association, either centrally or locally, can contribute towards public education in health." Several methods of developing the Association's activities in this connexion were discussed and recommendations were provisionally formulated for submission to the Public Health Committee.

During the week the Medical Secretary attended two meetings of considerable interest: on January 31st a meeting of the Executive, followed by a general meeting of the Post-Graduate Hostel, and on Thursday, February 3rd, a meeting of the Guthrie Society of the Westminster Hospital. At the first of these it was reluctantly decided to wind up the Hostel on account of want of support. The necessity for this decision is the more unfortunate in view of the growing need for such post-graduate facilities as the Hostel had hoped to supply—a need to which the correspondence in the Medical Department bears daily and increasing witness. At the meeting of the Guthrie Society the Medical Secretary spoke on the problems of medical practice. There was a good attendance of students, who showed keen interest in all that was said. On the afternoon of February 5th the Deputy Medical Secretary attended a meeting of the council of the British Pathologists' Association. This body, whose inaugural meeting was noted in the SUPPLEMENT of January 22nd, is approaching the British Medical Association with a view to full discussion of the probable extension of the National Health Insurance Acts to include the provision of pathological services, and the development of the schemes already being established throughout the country in this connexion. It is hoped that a plan applicable to the Insurance Committee areas throughout the country may be formulated. Among the items of interest dealt with in the course of routine correspondence in the Medical Department one merits individual reference. It is a point which has arisen in Durham, where a local lodge of the Miners' Association has expressed a wish to meet the local doctors with a view to reduction in the present contract rates for medical attendance, and has stated that payment will be in abeyance until such a meeting has been arranged. Local practitioners have been advised to resist any such reduction, and the lodge has been informed from headquarters that in doing so the local profession will have the full support of the Association.

Association Notices.

BRANCH AND DIVISION MEETINGS TO BE HELD.

BIRMINGHAM BRANCH: COVENTRY DIVISION.—At the meeting of the Coventry Division to be held on Tuesday, March 1st, Dr. A. T. W. Forrester will read a paper on "The diagnosis and treatment of early mental cases."

BIRMINGHAM BRANCH: NUNEATON AND TAMWORTH DIVISION.—A meeting of the Nuneaton and Tamworth Division will be held at the Tamworth General Hospital on Thursday, March 3rd, when Mr. A. B. Danby, F.R.C.S., will read a paper on obstetrics.

EAST YORK AND NORTH LINCOLN BRANCH: EAST YORK DIVISION.—At a meeting of the East York Division to be held at Powolny's Restaurant, Hull, on Friday, February 18th, Dr. H. Letheby Tidy will deliver a British Medical Association Lecture on "Glandular fever" at 9 p.m. The lecture will be preceded by an informal dinner for members of the Association.

EDINBURGH BRANCH.—The winter clinical meeting of the Edinburgh Branch will be held in the Royal Infirmary, Edinburgh, on Friday, February 25th. All members of the profession are cordially invited. Senior medical students desirous of attending will be admitted by card, obtainable from Mr. F. E. Jardine. The museum will be open from 10 a.m. to 6 p.m. Arrangements will be made for holding special clinics during the day. The clinical meeting will be held at 3.30. Those who have patients, specimens, etc., to show are requested to communicate with Mr. F. E. Jardine, F.R.C.S., 65, Northumberland Street, not later than February 17th. Dinner at 6.30 in the Scottish House of the Association, 6, Drumsheugh Gardens; morning dress; dinner ticket 10s. 6d. Members of the Branch are asked to notify the honorary secretaries not later than February 22nd whether or not they intend to be present.

GLASGOW AND WEST OF SCOTLAND BRANCH: LANARKSHIRE DIVISION.—A meeting of the Lanarkshire Division will be held at the County Hospital, Motherwell, on Tuesday, February 22nd, at 8.30 p.m., when Dr. John Reid will read a paper entitled "The fever hospital and the practitioner."

METROPOLITAN COUNTIES BRANCH: [illegible] are invited all fourth and fifth year stude[illegible] lified practitioners, will be held by the [illegible] Branch on Thursday, February 24th, at the [illegible] ation House, Tavistock Square, London, W.C., when an address will be given by Mr. E. B. Turner, F.R.C.S., on "Practice and types of patients." Tea and coffee at 5 p.m.; address at 5.30.

METROPOLITAN COUNTIES BRANCH: LEWISHAM DIVISION.—At a meeting of the Lewisham Division to be held at the Town Hall, Catford, S.E.6, on Tuesday, February 15th, at 8.15 p.m., Dr. Alfred Cox, the Medical Secretary, will deliver an address on "The medical profession in South Africa."

METROPOLITAN COUNTIES BRANCH: SOUTH-WEST ESSEX DIVISION.—A meeting of the South-West Essex Division will be held at Whipps Cross Hospital, Leytonstone, on Tuesday, March 1st, at 3.30 p.m., when Dr. J. C. Muir, medical superintendent of the hospital, will give a clinical demonstration.

METROPOLITAN COUNTIES BRANCH: WESTMINSTER AND HOLBORN DIVISION.—A meeting of the Westminster and Holborn Division will be held on Thursday, February 24th, at 8.45 p.m., at Romano's Restaurant, Strand. Dr. A. Abrahams, Dr. J. Benjafield, Dr. P. Doyne, Major M. Leahy, Mr. H. D. Gillies, Dr. M. Thompson, and other well known medical sportsmen have been invited to take part in a discussion on "Sport, its use and abuse." The meeting will be preceded by dinner at 7.30; the price will be 5s., payable at the table to the honorary secretary, to whom should be sent the names of those intending to be present.

METROPOLITAN COUNTIES BRANCH: WILLESDEN DIVISION.—A meeting of the Willesden Division will be held at the Willesden General Hospital, Harlesden Road, N.W.10, on Wednesday, February 16th, at 9 p.m. Mr. D. C. L. Fitzwilliams will read a paper on the tongue.

NORTH OF ENGLAND BRANCH.—The next scientific meeting of the North of England Branch will be held at the Royal Victoria Infirmary, Newcastle-on-Tyne, on Thursday, February 17th: 2.15 p.m., Mr. John Gilmour: "The problem of the spastic child"; 2.45 p.m., Dr. Wells Patterson: "Clinical evidence of subthyroidism"; 3.15 p.m., Mr. W. E. M. Wardill: "Some common conditions about the rectum and anus"; 3.45 p.m., tea; 4 p.m., Sir Robert Bolam: Dermatological cases; 4.30 p.m., Dr. Alex. McRae: "Sudden loss of sight."

NORTH OF ENGLAND BRANCH: SUNDERLAND DIVISION.—A meeting of the Sunderland Division will be held at the Royal Infirmary, Sunderland, on Wednesday, February 16th, at 8.15 p.m. Dr. A. Parkin will give an address on "Pleural effusion."

NORTH LANCASHIRE AND SOUTH WESTMORLAND BRANCH: LANCASTER DIVISION.—A meeting of the Division will be held on Wednesday, February 16th, at 8.30 p.m., somewhere in Lancaster. Members are requested to notify the secretary if they can attend on that date, and also if they will contribute to the programme by giving a short account of any interesting case they have had recently under their care.

NORTHERN COUNTIES OF SCOTLAND BRANCH.—A clinical meeting arranged by the Northern Counties of Scotland Branch will be held at Gray's Hospital, Elgin, on Friday, February 18th, at 3 p.m.; tea at 4.30.

It is hoped to arrange course of post-graduate lectures in the autumn to take the place a clinical meeting.

YORKSHIRE BRANCH: BRADFORD DIVISION.—On Wednesd February 23rd, Mr. N. Bishop Harman will deliver a Brit Medical Association Lecture to the Bradford Division entitl "The recognition of common eye disorders in general practice The lecture will be given at the Royal Infirmary at 8.30 p.m.

Meetings of Branches and Divisions.

NORTH OF ENGLAND BRANCH: HARTLEPOOLS DIVISION.

A MEETING of the Hartlepools Division was held in the Camer Hospital, West Hartlepool, on January 13th, when the chairma Dr. W. N. RISHWORTH, *M.C.*, presided.

Dr. GEORGE HALL, C.M.G. (Newcastle-on-Tyne), gave a lecture encephalitis lethargica. In the course of the lecture some historic facts were first touched upon, and then statistics given showing t incidence of the disease and its seasonal variation. The morb histology was discussed and illustrated, after which a series of cas was described, each showing the predominance of some speci symptom, while the sequelae in these and other cases were note Lantern slides illustrated many of the points touched upon. T lecture was followed by a discussion.

SOUTHERN BRANCH: PORTSMOUTH DIVISION.

A MEETING of the Portsmouth Division was held at the Queen Hotel, Southsea, on January 13th, when Dr. MEARNS FRASER w in the chair. On the proposition of the CHAIRMAN, supported many other members, hearty congratulations were conveyed the honorary secretary, Dr. H. H. Warren, upon the successf arrangements which had been made for the medical *souper dansa* which was held on January 11th.

Dr. THOMAS BEATON, O.B.E., medical superintendent of t Portsmouth Mental Hospital, gave an address on "The recognitio and management of mental patients." Dr. Beaton's addres which was most interesting, lucid, instructive, and of great pra tical value, was listened to with the closest attention. It w followed by a well sustained discussion which was taken part i amongst others, by Drs. JEANS, BOSWORTH WRIGHT, FORDE, LOC HART STEPHENS, GITTINGS, MCASKIE, MCELDOWNEY, and ASTON KE A hearty vote of thanks to the lecturer, proposed by Dr. GITTING seconded by Dr. MCASKIE, and enthusiastically carried, brought t a close one of the most successful and enjoyable meetings of th Division.

The total attendance numbered about fifty-five, of whom fort sat down to the supper preceding the meeting.

SUFFOLK BRANCH: SOUTH SUFFOLK DIVISION.

A MEETING of the South Suffolk Division was held at the Crow and Anchor Hotel, Ipswich, on December 3rd, 1926, with Dr H. N. BARON in the chair. After the transaction of Divisiona business a most helpful and interesting lecture on "Diseases an feeding of the new-born infant" was given by Dr. DONALL PATERSON, physican to out-patients, Hospital for Sick Children Great Ormond Street. A very hearty vote of thanks was accorde to Dr. Paterson for his address, and also to Dr. Baron for kindl providing tea.

SUSSEX BRANCH: BRIGHTON DIVISION.

A CLINICAL meeting of the Brighton Division was held at the Roya Sussex County Hospital on January 19th, Dr. DONALD HALL, the president, in the chair.

Dr. W. BROADBENT showed two cases illustrating the malaria treatment of general paralysis of the insane. Twelve malarial rigors had been allowed to occur, and the patients were then given quinine in daily doses of 10 grains. Both patients were much better after treatment.

Dr. DONALD HALL showed a case of congenital heart disease in a child, aged 3. The electro-cardiogram demonstrated a large Q.R.S. deflection and right-sided preponderance. The red blood cell count was 9,000,000 per c.mm. He also showed a man, aged 62, with generalized subcutaneous nodules. A section of a nodule indicated

that the condition was not carcinomatous, nor that of von Recklinghausen's disease. There was a slight suggestion of epithelioma, but no resemblance to any definite type of new growth. The patient had had pleurisy a year previously; he had been brought with a view to obtaining suggestions as to diagnosis, and Dr. Davis suggested the exclusion of the condition being secondary to myeloid tumour by radiographical examination of the small bones of the hands and elsewhere.

Mr. H. N. FLETCHER showed a case of pyonephrosis in a woman, which had commenced during her third pregnancy. After drainage by the ureteric catheter the temperature fell to normal and rigors ceased. When the catheter was removed the symptoms recurred, relief again following catheterization. Complete recovery ensued. He also presented three cases of exophthalmic goitre. In the first the condition was mild, but there was little or no improvement with medical treatment for two years. The pulse was 120 to 130, and there was marked tremor. Slight improvement followed tonsillectomy, but rapid benefit was produced by removal of the whole of one lobe and two-thirds of the other lobe of the thyroid gland. Only a trace of exophthalmos persisted; the patient was still excitable, but the tremor had disappeared. The two other cases were not very severe, but there had been marked exophthalmos, tachycardia, and tremor. A discussion followed on the technique of thyroidectomy, the anaesthetic employed, and the relative values of operation, *x* rays, and medical treatment; in this Dr. Donald Hall and Mr. F. E. Fielden took part.

Mr. J. R. H. TURTON showed a case of partial gastrectomy for carcinoma. The patient had progressed very well for twenty months after the operation, and had gained 2 st. in weight, but relapse and recurrence of the symptoms had followed Christmas fare. *X* rays showed no signs of new ulceration. He also showed a case of gastric ulcer, which had perforated twice: on the first occasion into the greater sac, and on the second into the lesser sac. Simple gastro-enterostomy was the only feasible operative treatment owing to the adhesions which were present.

Mr. FITZMAURICE-KELLY showed a case of tuberculous infection of the tonsil, and another of subspinous dislocation of the humerus. A single *x*-ray photograph showed the head of the humerus in an apparently normal position, while stereoscopic pictures revealed the true state of affairs.

Dr. DAVIS showed two cases of non-specific dermatitis herpetiformis. Rapid healing had followed one intravenous injection of novarsenobillon tried empirically.

Naval and Military Appointments.

ROYAL NAVAL MEDICAL SERVICE.

Surgeon Commander W. H. Hastings has been placed on the retired list at his own request, with the rank of Surgeon Captain.

Surgeon Commander J. P. Shorten, D.S.C., to the *Princess Margaret* on relief; B. S. Robson to the *Sandhurst*, temporary, additional; J. C. Souter to the *Princess Margaret*, temporary; W. W. D. Chilcott to the *President*, additional for R.N. Recruiting Headquarters, temporary, supernumerary.

Surgeon Lieutenant J. H. B. Crosbie promoted to the rank of Surgeon Lieutenant Commander.

Surgeon Lieutenants G. B. Tarring to the *Pembroke* for R.M. Infirmary, Chatham, temporary; H. M. Levy to the *Cricket*, additional; G. Phillips to the *Iron Duke* on arrival in home waters; J. A. Cusack to the *Victory* for R.M. Infirmary, Portsmouth, temporary.

ROYAL ARMY MEDICAL CORPS.

TESTS FOR DRUNKENNESS.

REPORT OF BRITISH MEDICAL ASSOCIATION'S COMMITTEE.

In October, 1925, the Council of the British Medical Association resolved to appoint a special committee to report and make recommendations on tests for drunkenness, and in the following December the personnel of the committee was completed. The Association was fortunate in securing the services of a number of persons of special experience and knowledge to aid in these deliberations. During 1926 the committee, under the chairmanship of Major-General Sir William Macpherson, held many sessions, and completed its terms of reference soon after the close of the year. The Council, at its meeting on February 9th, 1927, received the committee's report, of which the full text appears below, and gave authority for it to be published and put on sale without delay.

Introductory Note.

The Committee was appointed by the Council of the British Medical Association on 21st October, 1925, with the following reference:—

"To consider and report on the present tests for 'drunkenness' with recommendations as to their modification or improvement."

The Committee was constituted as follows and included representatives of general practitioners, police surgeons, magistrates, scientists and the Services:—

Sir Robert Bolam, F.R.C.P., LL.D. (Chairman of Council of the British Medical Association).
J. W. Bone, M.B. (Luton).
H. B. Brackenbury, M.R.C.S., L.R.C.P. (Chairman of Representative Body of the British Medical Association).
E. Farquhar Buzzard, F.R.C.P., M.D. (London).
J. A. R. Cairns (Metropolitan Magistrate).
E. Rowland Fothergill, M.B. (Hove).
R. F. Graham-Campbell, LL.M. (Metropolitan Magistrate).
N. Bishop Harman, F.R.C.S. (Treasurer of the British Medical Association).
R. Wallace Henry, M.D. (Leicester).
R. G. Hogarth, C.B.E., F.R.C.S. (President of the British Medical Association).
W. J. C. Keats, M.R.C.S., L.R.C.P., D.P.H. (Divisional Surgeon, Metropolitan Police).
Major-General Sir William Macpherson, K.C.M.G., C.B., LL.D., A.M.S. (ret.) (London).
A. R. Moore, M.B. (Divisional Surgeon, Metropolitan Police).
J. T. J. Morrison, F.R.C.S. (Consulting Surgeon, Birmingham Police).
T. Rose, M.R.C.S., L.R.C.P. (Divisional Surgeon, Metropolitan Police).
P. B. Spurgin, M.R.C.S., L.R.C.P. (Divisional Surgeon, Metropolitan Police).
E. B. Turner, F.R.C.S. (London).
Sir William Willcox, K.C.I.E., C.B., C.M.G., F.R.C.P. (London).

The Committee appointed as its Chairman Sir William Macpherson.

Origin of the Enquiry.

In the latter part of the year 1925 the attention of the Council of the British Medical Association was drawn to the wide publicity given in the lay press to cases of conviction in the Courts of persons charged with "drunkenness," especially in connection with motor car cases. The public, having its own idea of the significance of the word "drunk," was perplexed at the decisions given in certain cases and became confused by the varying standards of the tests applied.

Motorists in particular had a feeling of apprehension that they might at any time find themselves charged with a serious offence and that there was no certainty that the tests applied were of such a nature as to give them a fair chance of vindicating their personal reputation.

The Council had been informed that the Association of Metropolitan Police Surgeons had addressed itself to a revision of the tests, but had come to the conclusion that it would be better if the matter could be investigated and findings promulgated by a body such as the British Medical Association which is representative of all shades of professional opinion. The Council accordingly appointed this Committee.

General Considerations.

In approaching its work the Committee was fully aware that the subject was an exceedingly difficult one and that it was quite possible that no very definite and universally accepted results might accrue from its labours, but it was felt that good could not fail to emerge if the tests were revised by eliminating those which were the least reliable and by introducing new ones if possible, and, particularly, if a standard method of procedure could be drawn up which could be put into universal practice.

The Committee throughout its deliberations has kept prominently before it the fact that, though the immediate cause of its appointment was the prominence that has been given in the press to charges which have become more and more frequent with the increased use by the public of motor cars, —viz., "drunk in charge of a motor car"—these particular charges are a small proportion only of the charges involving "drunkenness" that come before the Courts. Moreover, only a proportion of the cases brought before police surgeons are certified as "drunk," and the number of cases upset on appeal

is small in comparison to the number which is convicted by the magistrates.

In any charge involving "drunkenness," the magistrate bases his decision on all relevant evidence, including that of any medical witnesses who may have been called. Occasionally an appeal is lodged, counsel being engaged, and one, or possibly more, eminent medical men called in who have had no opportunity of seeing the accused till some hours or even days after the alleged offence. A conflict of medical opinion frequently follows and the magistrate's decision may be upset. The Committee feels that such a state of affairs may lead to misconception.

Alcohol is not the only substance capable of producing symptoms of, or simulating, "drunkenness" as generally understood by the public, but the Committee decided to confine its deliberations to the investigation of tests for "drunkenness" caused by alcohol.

DEFINITION OF THE TERMS "DRUNK" AND "DRUNKENNESS."

Very careful consideration has been given to the question of a definition of these words. The definitions already laid down in standard works have been reviewed and the efforts of other bodies and individuals to arrive at a satisfactory expression have been considered.*

The words "drunk" and "drunkenness" have acquired a certain significance in the eyes of the law. This is unfortunate because of the absence of a statutory definition of these terms. In the first place, the effects of the ingestion of alcoholic beverages vary within very wide limits, not only in different individuals, but in the individual himself under differing conditions. Secondly, "drunkenness" cannot yet be measured by any definite standard, though the Committee is aware that scientific investigations, which are referred to later in this Report, are being carried out with a view to arriving at a standard of measurement. If it could be said without possibility of dispute that a man is "drunk" or "not drunk" in the same way that it can be said that a man is dead or not dead, the present difficulties would not have arisen.

This being so the Committee is of opinion that the word "drunk" should always be taken to mean that the person concerned was *so much under the influence of alcohol as to have lost control of his faculties to such an extent as to render him unable to execute safely the occupation on which he was engaged at the material time.* The adoption of this as a definition would clear away some of the difficulties in certain classes of case.

POLICE PROCEDURE.

The Committee has had under review the existing procedure in this and other countries in cases in which a charge of "drunkenness" is involved. (See Appendix I.)

Appendix II. shows the various offences in which "drunkenness" plays a part and the Acts under which offenders may be proceeded against. The Committee is indebted to Mr. Graham-Campbell for this information.

CLASSIFICATION OF TESTS.

The Committee having carefully considered the tests at present in use for establishing the fact that an individual is under the influence of alcohol, also those brought to notice by recent scientific research, has come to the conclusion that tests should be applied with a view to determining the following facts:—

A. Whether the person concerned has recently consumed alcohol.

B. Whether the person concerned is so much under the influence of alcohol as to have lost control of his faculties to such an extent as to render him unable to execute safely the occupation on which he was engaged at the material time.

C. Whether his state is due, wholly or partially, to a pathological condition which causes symptoms similar to those of alcoholic intoxication, irrespective of the amount of alcohol consumed.

The tests were consequently considered under each of these headings and conclusions arrived at as follows:—

1. Tests to Prove that a Person has Recently Consumed Alcohol.

(i.) For the purpose of determining whether or not a person has consumed alcoholic liquor there is no test of such ready application and practical value as "smell."

(ii.) The smell of alcoholic liquor in the breath or in vomited matter (if any) is a sign of the consumption of alcohol.

(iii.) A factor which must be borne in mind in regard to the smell of alcoholic liquor in the breath is that the intensity of the smell varies according to the nature of the liquor that has been consumed and to the time that has elapsed since its consumption.

(iv.) If there is no smell of alcoholic liquor in the breath of a person seen within a reasonable time after his arrest, it is improbable that he has recently consumed alcohol, and search should be made for some other cause of the condition concerning which an accusation has been made against him.

(v.) Keenness of the sense of smell varies in different individuals who may be applying this test. This fact must be taken into consideration, and also the fact that the smell of alcoholic liquor in the breath may be disguised by various substances.

2. Tests to Determine Impairment of Control of Faculties.

(i.) There are no tests universally applicable for determining the amount of alcohol which would render a person incapable of carrying on his occupation in a proper manner, as the effect of alcohol varies within wide limits in different individuals and in the same individual under differing conditions. Fine shades of self-control might be lost without any apparent signs of alcoholic intoxication.

(ii.) The first effect of alcohol is on the higher centres and is subjective, and even if no objective symptoms occur the subjective effect of alcohol may be sufficient to make it unsafe for an individual to be in a responsible position—for example, in charge of a mechanically propelled vehicle.

(iii.) There is NO SINGLE TEST TAKEN BY ITSELF which would justify a medical practitioner in deciding that the amount of alcohol consumed had caused a person to lose control of his faculties to such an extent as to render him unable to execute safely the occupation on which he was engaged at the material time. A correct conclusion can only be arrived at by the consideration of a combination of several tests and observations such as: General demeanour; state of the clothing; appearance of conjunctivae; state of the tongue; smell of the breath; character of the speech; manner of walking, turning sharply, sitting down and rising, picking up a pencil or coin from the floor; memory of incidents within the previous few hours, and estimation of their time intervals; reaction of the pupils; character of the breathing, especially in regard to hiccup.

(iv.) The following are tests upon which, taken by themselves, little stress should be laid in deciding whether or not a person is under the influence of alcohol: Presence of tachycardia (rapid pulse); repetition of set words or phrases; character of handwriting; walking along a straight line; failure of convergence of the eyes.

3. Tests for Pathological Conditions Simulating Alcoholic Intoxication.

(i.) The pathological conditions which may cause symptoms resembling those of alcoholic intoxication, irrespective of whether or not any alcoholic liquor has been consumed, come under certain of the following groups or diseases:—

Severe fevers.
Acute inflammatory lesions of the brain or the cerebral meninges.
Other less acute lesions of the central nervous system.
Mental and nervous disorders.
Diseases in which general metabolism is probably at fault.
The results of head injury.
Vascular lesions of the brain.
The acute effects of drugs.
The chronic effects of chemicals.
The effects of extremes of temperature.
Excessive loss of blood.
Stokes-Adams disease.
Sudden nervous shock.
Hysterical trance.
Auto-intoxication.
Acidosis.

(ii.) *Diagnosis* would have to be decided (a) by a clinical examination of the urine, including tests for pathological and toxicological abnormalities, and of the vomit (if any); (b) by an examination of the knee jerks and other reflexes, the pupils, retinæ, heart and organs of respiration; and (c) by an examination for signs of kidney disease and for signs of intra-cranial disease, such as retraction of the head and hemiplegia or any paralysis of the cranial nerves.

(iii.) THERE IS NO SINGLE SYMPTOM DUE TO THE CONSUMPTION OF ALCOHOLIC LIQUOR WHICH MAY NOT ALSO BE A SIGN OF SOME OTHER PATHOLOGICAL CONDITION.

---

* The Committee has noted that the Central Midwives Board in dealing with alleged "drunkenness" in midwives had difficulty in proving that a given person was "drunk." On the suggestion of the Chairman, Sir Francis Champneys, Bart., M.D., F.R.C.P., the phrase "the worse for drink" was substituted in framing charges, and he states that all difficulties have since disappeared.

The Committee learns that an effort to get rid of the word "drunk" when the Criminal Justice Bill was in Committee in the House of Commons failed because no really effective expression was put forward to take its place.

The Committee's attention has been drawn to the fact that the term "under the influence of drink" appears in the Children Act, 1908, and in the Inebriates Act, 1898.

4.—Tests based on Examination of the Blood, Urine, and Cerebro-spinal Fluid.

The Committee has reviewed the recent work that has been carried out with a view to detecting the presence of alcohol in the blood, urine and cerebro-spinal fluid. It has given careful consideration to the valuable research work carried out by Drs. Southgate and Carter,* with a view to estimating the amount of alcohol in the system by quantitative analysis of the urine.

The Committee is of opinion that, while this work is of great value from a scientific point of view, tests depending on examination of the blood, urine or cerebro-spinal fluid, are not practicable for the purpose now under consideration owing to the conditions limiting their application.

SUMMARY OF CONCLUSIONS AND RECOMMENDATIONS.

The Committee has arrived at the following general conclusions and recommendations in regard to persons accused of being "drunk":—

I. That the word "drunk" should always be taken to mean that the person concerned was so much under the influence of alcohol as to have lost control of his faculties to such an extent as to render him unable to execute safely the occupation on which he was engaged at the material time.

II. That it is desirable that a medical practitioner should base his opinion on the following considerations:—

(a) Whether the person concerned has recently consumed alcohol.

(b) Whether the person concerned is so much under the influence of alcohol as to have lost control of his faculties to such an extent as to render him unable to execute safely the occupation on which he was engaged at the material time.

(c) Whether his state is due, wholly or partially, to a pathological condition which causes symptoms similar to those of alcoholic intoxication, irrespective of the amount of alcohol consumed.

III. That in the absence of any pathological conditions a person is definitely under the influence of alcohol if there is a smell of alcoholic liquor in the breath and or in the vomited matter (if any) provided there is a combination of all or most of the following groups of signs or symptoms:—

(i.) A dry furred tongue, or conversely, excessive salivation.

(ii.) Irregularities in behaviour, such as insolence, abusive language, loquacity, excitement or sullenness, and disorder of dress.

(iii.) Suffusion of the conjunctivæ and reaction of pupils. The pupils may vary from a state of extreme dilatation to extreme contraction, and may be equal or unequal.†

(iv.) Loss or confusion of memory, particularly as regards recent events and appreciation of time.

(v.) Hesitancy and thickness in speech and impaired articulation.

(vi.) Tremors and errors of co-ordination and orientation.

IV. That there is no single test by itself which would justify a medical practitioner in deciding that the amount of alcohol consumed had caused a person to lose control of his faculties to such an extent as to render him unable to execute safely the occupation on which he was engaged at the material time. A correct conclusion can only be arrived at by the result of the consideration of a combination of several tests or observations such as:—

General demeanour;
State of the clothing;
Appearance of conjunctivæ;
State of the tongue;
Smell of the breath;
Character of the speech;
Manner of walking, turning sharply, sitting down and rising, picking up a pencil or coin from the floor;
Memory of incidents within the previous few hours, and estimation of their time intervals;
Reaction of the pupils;
Character of the breathing, especially in regard to hiccup.

V. That the following are tests upon which, taken by themselves, little stress should be laid in deciding whether or not a person is under the influence of alcohol:—

Presence of tachycardia (rapid pulse);
Repetition of set words or phrases;
Character of handwriting;
Walking along a straight line;
Failure of convergence of the eyes.

VI. That in ordinary circumstances any person accused of "drunkenness" should be able to rely upon being seen by a doctor, if he so desires, within half an hour of the time at which he is charged.

VII. That analyses of the blood, urine and cerebro-spinal fluid for estimating the amount of alcohol consumed are not practicable in connection with the examination of persons charged with "drunkenness" owing to the conditions limiting their application.

VIII. That with a view to uniformity in the method of testing for "drunkenness" some such form of certificate as that drawn up by the Danish Medico-Legal Society might well be adopted for general use in this country. (See Appendix I.)

APPENDIX I.

MEMORANDUM ON PROCEDURE USUALLY ADOPTED IN DEALING WITH CASES OF ALLEGED "DRUNKENNESS."

I.—POLICE PROCEDURE IN GREAT BRITAIN.

The following procedure has been submitted to the Committee as fairly typical of what happens in London and most of the larger towns:—

In cases of "drunkenness" apart from those cases in which the accused person is in charge of a vehicle, the charge is made by the station officer. If the accused person disputes the charge, the divisional surgeon is sent for. The accused is informed that this has been done and that he has the right to call another doctor, of his own selection, on the definite understanding that the police will not be responsible for any fee incurred for such attendance. In the Metropolitan Police area the divisional surgeon is not sent for as a matter of routine. The divisional surgeon, or his deputy, will in all cases be present when an accused person is examined by another doctor. The latter, after his examination, is asked to write his opinion beneath that previously made by the divisional surgeon in the surgeon's book. A copy of this report is written on a special form by the station officer and attached to the charge sheet.

In all cases of "drunkenness" where the driver of any vehicle is concerned, the divisional surgeon is sent for, whether the condition is disputed or not. The divisional surgeon informs the accused person of the result of his examination. The accused person or his representative has the right to call another doctor, under the conditions mentioned above.

The tests usually employed may be divided into two main groups:—

(a) Data tending to establish the fact that alcohol has been taken.

1. Smell of alcohol in the breath.
2. Suffusion of the conjunctivae—in simple language, watering and redness of the whites of the eyes.
3. Flushed face.
4. Tachycardia (rapidity of the pulse).
5. Admission of having taken alcohol.
6. Certain abnormal conditions of tongue and lips.
7. Certain abnormal conditions of the pupils.
8. Presence of tremors.

(b) Tests designed to determine whether or not the amount taken has disturbed the normal behaviour of the accused.

1. Memory tests—accused is asked simple questions such as date and time of day; where he lives, what he was doing prior to arrest, and where he now is.
2. Visual tests.
3. Speech test—accused is induced to talk and his manner of talking is noted. Some police surgeons ask him to spell words or to say catch phrases such as "truly rural" or "fish sauce shop."
4. Co-ordination tests (ability to perform combined movements). These include approaching and picking up a small object from the floor or table; selecting a chair and sitting upon it and getting up again; ability to stand steady with heels together and eyes shut; walking away and returning; walking along a chalk line.
5. Writing tests.

These tests are also designed to eliminate physical illness or disability. The presence of artificial eyes, limbs or teeth,

* BRITISH MEDICAL JOURNAL, March 13th, 1926, p. 463.

† In the opinion of many police surgeons when alcohol in toxic quantity has been consumed, the pupil reflex to *ordinary light* is absent, whereas the pupil will contract in a *bright light* and remain contracted for an abnormally long time, indicating delayed reaction of the pupil.

the presence of any of which may cause a person's behaviour to vary from the normal, are also noted. The general appearance and deportment are observed, particularly with regard to disorder of clothing.

If the police surgeon is satisfied that the accused is "drunk" and gives a certificate to that effect the case comes before the magistrate. Should a conviction result there is a right of appeal.

If however the police surgeon has any doubt as to whether the accused is "drunk" the accused invariably gets the benefit of the doubt and is discharged at once unless some further charge is preferred at the same time.

In London and in nearly all large provincial towns there are duly appointed police surgeons, and proximity of residence to the police station is often a determining factor in their appointment.

The average time that elapses before the accused is seen by the police surgeon is approximately thirty minutes after the charge is preferred.

In those places where there is no appointed surgeon and where the accused's own doctor is sent for, or failing him, the nearest doctor, much depends on the distance to be covered. Any doctor so summoned would, if available, attend at once and the average time would probably approximate to that mentioned above.

II.—Procedure in the Royal Navy.

The following information is extracted from the *Journal of the Royal Naval Medical Service*, October, 1926 :—

"*Drunkenness—Medical Examination of Persons suspected of. (N.L. 2173/26.—24.9.1926.)*

1. Though the decision in the first instance in cases of alleged drunkenness whether a person is in a fit state to perform his duty rests with the commanding officer, the medical officer may be required to give his opinion on the question if he has been called in to examine the accused. If so called in the medical officer must also determine whether the condition of the accused can be accounted for wholly or in part by disease or injury. The accused may be suffering from some disease of which he is unaware and serious results may follow if he is not kept under medical supervision. On the other hand, a plea of sickness, injury, or nervous disturbance may be brought forward at a court-martial, and the medical officer may be asked whether any such condition was actually present when he examined the accused. For these reasons the medical officer when called in to examine any person accused of drunkenness should perform a complete and comprehensive examination at once, whether the accused complains of any disability or not. He should take a detailed history of the case, observe every feature of the person's demeanour and behaviour, and examine every system of the body. Complete notes should be made in writing at the time.

2. The medical officer should endeavour to formulate answers to the following questions upon any of which he may be required to give an opinion which can be maintained during a searching cross-examination :—

(1) Is the condition and behaviour of the accused normal or abnormal?
(2) Is he fit to perform his duty?
(3) If his condition or behaviour is abnormal, is the abnormality wholly due to consumption of alcohol?
(4) Is the abnormality partly due to consumption of alcohol?
(5) Is the abnormality wholly due to disease or injury?
(6) Is the abnormality partly due to disease or injury?
(7) If the abnormality is partly due to consumption of alcohol and partly to disease or injury, what is the relative importance of these factors?
(8) Is the accused drunk as defined for naval purposes in K.R. and A.I. Article 462a?*

3. If a court-martial follow, the medical officer should be able to give a definite answer to each of these questions and to support his opinion by facts observed by himself at the time. Courts-martial are recommended to put to the medical officer any such questions which have not been answered in examination or cross-examination, and to require him to state the facts upon which he bases his opinion in each case."

III.—Procedure in the Army.

King's Regulations. Para. 534:—"A private soldier who is drunk is to be placed in close arrest, alone, if possible, in a guard detention room. He may be deprived of his boots except when the weather is cold and he is likely to suffer in consequence. He is to be visited and his condition ascertained at least every two hours by a N.C.O. of the guard and escort. Should any symptoms of serious illness be observed, a medical officer is forthwith to be sent for. A soldier suspected of being drunk is not to be put throu any drill or tested for the purpose of ascertaining his con tion. A soldier charged with drunkenness is not to be broug before an officer for investigation of the charge until he properly sober. For this purpose twenty-four hours shou usually be allowed to elapse before the investigation."

IV.—Procedure in the Royal Air Force.

King's Regulations. Para. 1076(n) and Air Council Instru tions for the R.A.F.:—"An airman suspected of being dru will not be put through any drill or tested for the purpo of ascertaining his condition."

V.—Procedure in other Countries.

Denmark.

The Danish Medico-Legal Society has designed an order classification of tests which, when methodically carried ou take the police surgeon about forty-five minutes per ca including the making of written notes, and at the reque of the Copenhagen police has drawn up a form of medic certificate based on a number of the generally used clinic examination methods with which every medical practition should be acquainted. This certificate was promptly adopt by other jurisdictions in the country and in 1925 was ma an order by the Ministry of Justice.

In co-operation with the police the Danish Medico-Leg Society has decided that it would be impracticable to car out tests based on examination of urine or blood.

In Copenhagen, the police employ an expert medical m who is available for this work at any hour of the day night and who is able to investigate a given case immediatel All cases involving a charge of "drunkenness in charge a motor-car" are submitted to this expert.

Medical Certificate adopted by the Ministry of Justice of Denmark.

The wording of the form drawn up by the Danish Medic Legal Council and adopted by the Ministry of Justice Denmark is as follows :—

Name, address, occupation, and age of the person examine
Place of examination and exact time.
1. What is the appearance of the person under examinatio (Dozy, heavy eyelids, flaccid features, congestion of face a the conjunctiva of the eyes, perspiration, slobbering, hiccu vomiting, clothes disarranged, signs of vomiting on clothes, etc.
2. How is his manner? (Noisy, elated, arrogant, doltish, hig spirits, garrulous, unsteady, indolent, etc.)
3. Does he know where he is and what time it is? (If in th affirmative, to be answered by "yes"; otherwise the remark made to be inserted.)
4. (a) How is the memory? (Particularly with respect t doings during the last few hours. Try whether he can impri on his mind a couple of street addresses.)
(b) [illegible] (The person examined to be asked t [illegible] at the accident, or perhaps to describ [illegible] paper shown him.)
(c) Calculation tests.
5. How is the speech? (Thick, snuffling, lisping, stammering faltering. The person under examination is asked to repea difficult words, read a small notice from a newspaper or the like.
6. How is the gait? (Lurching, shuffling, straddling, o characterised by ataxy. Romberg's test may be tried, turnin round and the like.)
7. (a) Steadiness of gestures with the hand. (Finger-to-finge test, picking up of objects from the floor, and the like.)
(b) Handwriting. (The party under examination to write hi name, age, occupation, and residence.)
8. Pulse (regularity, frequency). Pupils (size, reaction agains light). Susceptibility to pain (numbness).
9. Does the party under examination smell of liquor?
10. Are there any signs of illness (epilepsy, apoplexy, traumatism, shock, etc.) or great emotion, weariness, etc.?
11. Other observations (including the remarks of the persor charged respecting his consumption of liquor during the last twenty-four hours).

Conclusion.

(a) Have symptoms appeared during the examination tending to indicate that the condition of the person examined is not normal?
(b) Must it be assumed that the symptoms displayed are a consequence of the consumption of alcohol?
(c) Would you describe the condition of the person examined as "intoxicated"?

Signature.....

New Zealand.

In all convictions for offences connected with "drunkenness" an appeal is allowed provided that a fine in excess of £5 has been inflicted, or in motor car cases, if the licence has been suspended or the defendant disqualified from obtaining the licence. An appeal may also be allowed on a point of law. It is understood that appeals are extremely rare.

* K.R. and A.I. Article 462a is as follows: The proper meaning to be attributed to the word "drunk" is "that through the intoxicating effect of liquor the accused was unfit to be entrusted with his duty."

Procedure in connection with persons arrested on charges involving "drunkenness" is much the same as in the United Kingdom. If the accused wishes to see a doctor he may on demand see his own doctor provided he is able to pay the fee or else be seen by the police surgeon. Failing a demand on the part of the accused to see a doctor it is the police inspector who decides whether a doctor should be called in or not. The police are very carefully instructed as to how to deal with persons when a question of "drunkenness" arises and are always expected to give the accused the benefit of any doubt.

France.

The French law does not provide for cases of slight drunkenness on the part of persons driving motor cars, and the point has never been raised in any decision of the Courts. So long, therefore, as the driver of the car is not manifestly drunk he cannot be prosecuted for this fact alone, and if prosecuted on another count, it cannot constitute legally an aggravating circumstance.

Consequently, if whilst slightly under the influence of drink the driver of a car meets with an accident or exceeds the speed limit, he will only be prosecuted in respect of the latter offence. If the judge is satisfied that without being manifestly, he was slightly, drunk, he will probably inflict upon him the highest penalty provided for the offence in respect of which he was indicted, although it is a matter entirely left to his discretion.

So far as the method of detecting cases of "drunkenness" is concerned, nothing has ever been prescribed either by law or by custom, and such cases can only therefore be proved by the mere oral evidence of eye-witnesses.

United States of America.

The following is a copy of the official form used by surgeons of the police department of New York in examining a member of the Force who is alleged to be suffering from over-indulgence in some intoxicating agent or agents:—

United States Navy.—The Department of the United States Navy has under consideration the question of providing definite instructions for its medical officers with reference to determining the nature of the mental and physical condition of those suspected of being under the influence of an intoxicant. The guiding principle at present in force in the United States Navy is whether or not the intoxication is "sufficient sensibly to impair the rational and full exercise of the mental and physical faculties."

APPENDIX II.

MEMORANDUM ON OFFENCES IN WHICH "DRUNKENNESS" PLAYS A PART.

The object of this memorandum is to present a list of those offences in respect of which a doctor might be asked to express an opinion as to the sobriety (I.) of a defendant; (II.) of some other person than the defendant; and under (III.) and (IV.) in certain other cases where, although no actual offence has been committed, a similar question might arise.

The following expressions are used in the sections referred to:—"drunk," "drunken," "drunkenness," "under the influence of drink," "in a state of intoxication," "of intemperate habits."

The definition of "habitual drunkard" in the Inebriates Act, 1879, indicates that in law the word "drunk" connotes the "drinking of intoxicating liquor."

I. OFFENCES COMMITTED BY A DRUNKEN PERSON.

(a) That may be committed by any person.

(1) Licensing Act, 1872 (35 and 36 Vict., c. 94, s. 12).

Found drunk in any highway or other public place, whether a building or not, or on any licensed premises.

Being guilty while drunk in any highway or other public place of riotous or disorderly behaviour.

Being drunk while in charge on any public highway or other public place of any carriage, horse, cattle, steam engine.

Being drunk while in possession of any loaded firearms.

(2) Metropolitan Police Act, 1839 (2 & 3 Vict., c. 47, s. 58).

Person found drunk in any street or public thoroughfare within the Metropolitan Police District who while drunk is guilty of any riotous or indecent behaviour.

(3) Town Police Clauses Act, 1847 (10 & 11 Vict., c. 89, s 29).

Person drunk in any street and guilty of any riotous or indecent behaviour therein.

(4) Licensing Act, 1902 (2 Edwd. VII, c. 28, s. 2).

Found drunk in any highway, other public place whether a building or not, or any licensed premises, while having the charge of a child under the age of 7 years.

(5) Criminal Justice Act, 1925 (15 & 16 Geo. V, c. 86, s. 40).

From June 1st, 1926: Person drunk while in charge on any highway or other public place of any mechanically propelled vehicle.

(6) Licensing (Consolidation) Act, 1910 (10 Edwd. VII, & 1 Geo. V, c. 24, s. 80).

Drunken person refusing or failing to quit licensed premises upon being requested to do so by the holder of the license or his agent or servant.

(7) Refreshment Houses Act, 1860 (23 & 24 Vict., c. 27, s. 41).

Being drunk in any shop house premises or place licensed for refreshments and entertainment under the provisions of the Act, and refusing to quit such shop premises or place upon being requested so to do by the manager or the occupier or his agent or servant or by any constable.

(8) Merchant Shipping Act, 1894 (57 & 58 Vict., c. 60, s. 287).

Drunk and disorderly person who has been refused admittance to a passenger steamer and persists in attempting to enter that steamer.

Person drunk and disorderly in a steamer refusing to leave the steamer at any place in the United Kingdom where he can conveniently do so when requested by the owner or any person in his employment.

(9) Children Act, 1908 (8 Edwd. VII, c. 67, s. 13).

Where death of infant under 3 years of age was caused by suffocation (not caused by disease or a foreign body) whilst in bed with some person over 16 years of age and that person at the time of going to bed was under the influence of drink, such person deemed to have neglected the infant in a manner likely to cause injury to its health (under s. 12).

(10) Tramways Act, 1870 (33 & 34 Vict., c. 78).

Power to make By-laws (s. 46) and to impose penalty for breach (s. 47).

Many authorities have By-law against drunken person entering.

L.C.C. (under their own Acts) have By-law: "Any person who is in a state of intoxication . . . shall not enter or mount upon any car." Must leave upon request.

(11) See under (III.) Habitual Drunkenness.

(b) Offences that can be committed only by persons in a specified capacity.

(1) Air Force Act, 1917 (7 & 8 Geo. V, c. 51, s. 12).

Provisions of Army Act are applied to Air Force (see Army Act below).

(2) Army Act, 1881 (44 & 45 Vict., c. 58) (as amended.)

S. 19. Any person subject to Military Law who is drunk, whether on duty or off duty, commits an offence.

S. 44. (7) Aggravated offence of drunkenness defined: (a) committed on the march or otherwise on duty; (b) after being warned for duty; (c) if after being warned for duty is unfit for duty.

(3) London Hackney Carriage Act, 1843 (6 & 7 Vict., c. 86).

S. 28. Being drunk during employment as a driver of hackney carriages or as a driver or conductor of a stage carriage in the Metropolitan Police District.

(4) London Hackney Carriage Act, 1831 (1 & 2 William IV, c. 22).

S. 56. Proprietor or driver or any other person having care of hackney carriage who shall by intoxication . . . injure or endanger any person in his life, limbs, or property.

(5) Town Police Clauses Act, 1847 (10 & 11 Vict., c. 89, s. 61).

The driver or person having the care of any carriage being intoxicated while driving.

(6) Merchant Shipping Act, 1894 (57 & 58 Vict., c. 60).

S. 220. Master, seaman or apprentice belonging to a British ship . . . by reason of drunkenness (a) *doing any act tending* to loss, etc., of ship, or to endanger life or limb of a person belonging to or on board ship; (b) refusing or omitting to do any lawful act . . . for preserving the ship . . . or any person . . . from danger.

S. 607. Pilot when in charge of a ship . . . by reason of drunkenness (a) doing, or (b) refusing (as in s. 220).

S. 407 (1) (b) "Court of Enquiry" as to conduct of a master, mate, or engineer, if they find he has been guilty of any . . . gross act . . . of drunkenness . . . may cancel or suspend certificate.

(7) Naval Discipline Act, 1866 (29 & 30 Vict., c. 109, s. 27).

Every person subject to Act . . . guilty of drunkenness commits an offence.

(8) Poor Relief Act, 1814-15 (55 Geo. III, c. 137, s. 51).

Any person maintained in any workhouse guilty of drunkenness.

(9) Post Office Act, 1908 (8 Edwd. VII, c. 48, s. 57 (b)).

Any person employed to convey or deliver a mail bag, or a postal packet in course of transmission by post . . . guilty of any act of drunkenness whilst so employed.

(10) Railway Regulation Act, 1840 (3 & 4 Vict., c. 97, s. 13).

Any engine driver, guard, porter, or other servant in the employ of any Railway Company found drunk while in the employ of the Railway Company.

(II.) OFFENCES COMMITTED IN RESPECT OF A DRUNKEN PERSON.

(1) Licensing Act, 1902 (2 Edwd. VII, c. 18, s. 7).

Any person who being on any premises licensed for the sale of any intoxicating liquor . . . procures or attempts to procure any intoxicating liquor for consumption by any drunken person.

Aiding and abetting any drunken person in obtaining or consuming any intoxicating liquor on any premises so licensed as aforesaid.

(2) Licensing (Consolidation) Act, 1910 (10 Edwd. VII, & 1 Geo. V, c. 24, s. 75).

The holder of a Justices licence shall not permit drunkenness to take place on his premises, or sell any intoxicating liquor to a drunken person.

(3) Refreshment Houses Act, 1860 (23 & 24 Vict., c. 27, s. 32).

Person licensed to keep refreshment house who shall knowingly suffer drunken persons to assemble or continue in or upon his premises.

(4) Firearms Act, 1920 (10 & 11 Geo. V, c. 43, s. 4).

A person shall not sell a firearm or ammunition to or repair, prove, or test a firearm or ammunition for, any person whom he knows, or has reasonable ground for believing, to be drunk . . .

(5) Pawnbrokers Act, 1872 (35 & 36 Vict., c. 93, s. 32).

Pawnbroker taking article in pawn from any person appearing to be intoxicated.

(III.) HABITUAL DRUNKENNESS.

(1) Inebriates Act, 1879 (42 & 43 Vict., c. 19, s. 3).

Defines "Habitual Drunkard" as a "person who not being amendable to any jurisdiction in lunacy is notwithstanding by reason of habitual intemperate drinking of intoxicating liquor at times dangerous to himself or herself or to others, or incapable of managing himself or herself, and his or her affairs."

(2) Inebriates Act, 1898 (61 & 62 Vict., c. 60, s. 1).

Any person convicted on indictment of an offence punishable with imprisonment or penal servitude, if offence committed under influence of drink, or drunkenness a contributory cause, and offender is an habitual drunkard—may be detained in inebriates reformatory.

S. 2. Any person committing an offence of drunkenness after three previous convictions of any similar offence—and who is an habitual drunkard—may be sent to inebriates reformatory.

(3) Children Act, 1908 (8 Edwd. VII, c. 67, s. 26).

Where a person convicted of offence of cruelty or of any offence under Schedule I is an habitual drunkard, Court may order him to be detained in inebriates reformatory for not exceeding two years.

(4) Summary Jurisdiction (Married Women) Acts, 1895 to 1925.

A married woman may obtain order or orders on ground of habitual drunkenness of husband and vice versa.

(IV.) OTHER ACTS.

(1) Firearms Act, 1920 (10 & 11 Geo. V, c. 43, s. 1 (2) (

A firearm certificate is not to be granted to a person wl the Chief Officer of Police has reason to believe to be of intemperate habits.

(2) Licensing (Consolidation) Act, 1910 (10 Edwd. VII, c. s. 95 (c)).

A club may be struck off the register or ground that t is "frequent drunkenness" on the premises.

APPENDIX III.

PUBLICATIONS CONSIDERED BY THE COMMITT

Among the documents considered by the Committee, w *the following:—*

(1) Address by Sir James Purves-Stewart, K.C.M.G., C.B., M.D., F.R.C on March 1st, 1925, before the Society for the Study of Inebriety, enti "Acute drunkenness: Its medico-legal aspects, symptoms, and tests."

(2) Article by H. W. Southgate, M.B., B.Sc., and Godfrey Carter, M D.P.H., entitled "Excretion of alcohol in the urine as a guide to alcoh intoxication." (BRITISH MEDICAL JOURNAL, March 13th, 1926, pp. 453-

(3) Pamphlet issued by the True Temperance Scientific Commi entitled "The problem of the intoxicated motor driver."

(4) Extract from "French's Differential Diagnosis in Coma," on pathological conditions which cause symptoms similar to those of alcoh intoxication, irrespective of whether any alcohol has been consumed or

British Medical Association.

CURRENT NOTES.

Annual Meeting of the American Medical Association.

THE seventy-eighth annual session of the American Medi Association will be held in Washington from May 1 to 20th inclusive, and the Council of the Brit Medical Association has been invited to appoint offic delegates. The Medical Secretary will be glad to know any member of the Association who is likely to be visiti the United States at that time.

Some Work of the Week.

The chief event of the week beginning on February 7 was the Council meeting, which occupied the whole Wednesday. The customary report of the discussions this meeting, which ended at about 7 o'clock, will appe in next week's SUPPLEMENT. The Committee on Puerpe Morbidity and Mortality met on February 11th, and co tinued its examination of the information supplied institutions and individuals throughout the country. T impossibility of securing uniform reports makes the wo of collation and evaluation difficult. The day before t meeting of Council the Medical Secretary attended meeting of the Welsh Contract Practice Subcommittee Cardiff. The subcommittee was considering the desirabili of approaching the miners of South Wales in the matter the arrears in the doctors' remuneration caused by the lo strike. There was a good discussion, and it was resolv to call a meeting of colliery and works doctors in Sou Wales on Saturday, March 12th. In pursuit of the Ass ciation's general policy of keeping in touch with the medic schools, the Medical Secretary spoke on the problems medical practice at a meeting of the St. Thomas's Hospit Medical and Physical Society on Thursday evening. The was a good attendance, and the audience showed gre interest in Dr. Cox's description of the various kinds o medical practice and the ordinary everyday problem affecting each. Dr. M. A. Cassidy was in the chair. O February 11th the Deputy Medical Secretary, Dr. Anderso attended the annual dinner of the Hastings Division at th Royal Victoria Hotel, St. Leonards, and responded to th toast of the British Medical Association. It is the custo of the Hastings Division to invite to this dinner all th more prominent people in the area, and on this occasio the numerous guests included the Chairman of the Publi Health Committee, the Bishop of Lewes (who is honorar chaplain to the Division), the Chief Constable, Mr. F Britten Austin, author and playwright, and the secretar of the local section of the British Dental Association. Th dinner was, as usual, very successful.

The headquarters correspondence during this and th last few weeks has shown a significant increase in th

number of inquiries touching upon different aspects of the hospital policy of the Association. These inquiries show that the profession is becoming alive to the dangers involved in the present position, and more especially to the progressive effect upon hospital and private practice of the numerous contributory schemes now in force. The majority of the points raised are covered by the published policy of the Association, the general adoption of which would solve many of the problems now exercising the minds of hospital staffs throughout the country.

A typical example of the value to an individual of advice from the central office is supplied by correspondence with a member who is medical officer to a workhouse infirmary. He informed the Medical Secretary that on two occasions the coroner had refused to pay his salaried partner for giving evidence at inquests in respect of accident cases sent to the infirmary by the latter. Payment was refused on the ground that the principal was medical officer to the infirmary. The doctor concerned having acted independently and not for his chief, he was advised that he was entitled to and should press for payment. He thereupon took the case up with the county council, and now reports that the fees have been paid.

The Association's Annual Handbook.

Copies of the *Annual Handbook of the British Medical Association* for 1926-27 are available for members and others. Primarily intended as a book of reference for honorary secretaries and other workers of the Association, the *Handbook* is also of interest and assistance to all members. The new edition has been completely revised. It contains the decisions of the Representative Body of the Association on matters of policy: information as to the constitution of the Association; particulars of the new London and Scottish Houses of the Association; information as to the BRITISH MEDICAL JOURNAL, the circulation of which is now over 35,000 copies weekly, and other publications of the Association; and lists of the Council, central committees, officers, and officials of the Association. It also contains a great deal of general information as to the work of, and facilities offered by, the Association. Copies of the *Handbook* can be had by members, *gratis* and post free, on application to the Medical Secretary, British Medical Association House, Tavistock Square, London, W.C.1. To non-members the book is on sale at 3s. 6d. (post free 3s. 9½d.).

Association Notices.

VACANCY IN COUNCIL, 1926-27.

A VACANCY occurs in the membership of the Council owing to the death of Dr. T. Ridley Bailey, of Bilston, Staffs, who was elected one of the "24" Members of Council by the members of the Birmingham and Staffordshire Branches, the term of office lapsing July, 1927.

Nominations in respect of the vacancy are required to be either (*a*) by a Division comprised in the above-mentioned Branches or (*b*) by not less than three members of those Branches. Forms of nomination will be forwarded on application to the Medical Secretary, B.M.A. House, Tavistock Square, London, W.C.1, and must be returned so as to reach him not later than the first post on Monday, March 7th, 1927. In the event of more than one candidate being nominated for the vacancy, voting papers will be issued to the electors not later than Saturday, March 12th, 1927, and must be returned so as to reach the Medical Secretary not later than the first post on Friday, March 18th, 1927.

The result of the voting, if any, will be published in the SUPPLEMENT of March 26th.

SOUTH WALES AND MONMOUTHSHIRE, AND WORCESTERSHIRE AND HEREFORDSHIRE BRANCHES.

HEREFORD AND MONMOUTHSHIRE DIVISIONS.

THE following change has been made by the Council of the Association and takes effect as from the date of publication of this notice:

That the civil parish of Skenfrith be transferred from the Monmouthshire Division of the South Wales and Monmouthshire Branch to the Hereford Division of the Worcestershire and Herefordshire Branch.

February 19th, 1927. ALFRED COX, *Medical Secretary.*

BRANCH AND DIVISION MEETINGS TO BE HELD.

BATH AND BRISTOL BRANCH.—A meeting of the Bath and Bristol Branch will be held at the Red House, Bath, on Wednesday, February 23rd, at 8.15 p.m. Dr. Robert Hutchison will deliver an address on dyspepsia, which will be followed by a discussion.

BIRMINGHAM BRANCH: COVENTRY DIVISION.—At the meeting of the Coventry Division to be held on Tuesday, March 1st, Dr. A. T. W. Forrester will read a paper on "The diagnosis and treatment of early mental cases."

BIRMINGHAM BRANCH: NUNEATON AND TAMWORTH DIVISION.—A meeting of the Nuneaton and Tamworth Division will be held at the Tamworth General Hospital on Thursday, March 3rd, when Mr. A. B. Danby, F.R.C.S., will read a paper on obstetrics.

DORSET AND WEST HANTS BRANCH: BOURNEMOUTH DIVISION.—The annual dinner of the Bournemouth Division will be held at the Royal Bath Hotel, on Thursday, March 3rd, and not as previously stated. It is hoped that members will keep this date free and will bring guests, including ladies.

DORSET AND WEST HANTS BRANCH: WEST DORSET DIVISION.—A meeting of the West Dorset Division will be held at the Parish Room, Blandford, on Tuesday, February 22nd, at 2.30 p.m. Professor G. E. Gask, C.M.G., D.S.O., director of the surgical professorial unit of St. Bartholomew's Hospital, will deliver a British Medical Association Lecture entitled "The therapeutic value of operations for gastric ulcer," illustrated by lantern slides. Cases will be shown by the staff of the Blandford Cottage Hospital. Tea will be served afterwards by the courtesy of Dr. Kenneth Wilson. Members are requested to note the date and make a special effort to be present.

EAST YORK AND NORTH LINCOLN BRANCH: EAST YORK DIVISION.—At a meeting of the East York Division to be held at Powolny's Restaurant, Hull, to-day (Friday, February 18th), Dr. H. Letheby Tidy will deliver a British Medical Association Lecture on "Glandular fever" at 9 p.m. The lecture will be preceded by an informal dinner for members of the Association.

EDINBURGH BRANCH.—The winter clinical meeting of the Edinburgh Branch will be held in the Royal Infirmary, Edinburgh, on Friday, February 25th. All members of the profession are cordially invited. Senior medical students desirous of attending will be admitted by card, obtainable from Mr. F. E. Jardine. The museum will be open from 10 a.m. to 6 p.m. Arrangements will be made for holding special clinics during the day. The clinical meeting will be held at 3.30. Dinner at 6.30 in the Scottish House of the Association, 6, Drumsheugh Gardens; morning dress; dinner ticket 10s. 6d. Members of the Branch are asked to notify the honorary secretaries not later than February 22nd whether or not they intend to be present.

GLASGOW AND WEST OF SCOTLAND BRANCH: LANARKSHIRE DIVISION.—A meeting of the Lanarkshire Division will be held at the County Hospital, Motherwell, on Tuesday, February 22nd, at 8.30 p.m., when Dr. John Reid will read a paper entitled "The fever hospital and the practitioner."

LANCASHIRE AND CHESHIRE BRANCH: HYDE DIVISION.—At the meeting of the Hyde Division to be held in the Stalybridge Town Hall on Thursday, February 24th, at 8.30 p.m., an address will be delivered by Dr. F. Craven Moore of Manchester on "The early diagnosis of cancer of the stomach." The Executive Committee hope that all members will attend and bring their medical friends.

METROPOLITAN COUNTIES BRANCH.—A meeting, to which are invited all fourth and fifth year students and recently qualified practitioners, will be held by the Metropolitan Counties Branch on Thursday, February 24th, at the British Medical Association House, Tavistock Square, London, W.C., when an address will be given by Mr. E. B. Turner, F.R.C.S., on "Practice and types of patients." Tea and coffee at 5 p.m.; address at 5.30.

METROPOLITAN COUNTIES BRANCH: CITY DIVISION.—A meeting of the City Division will be held at the Metropolitan Hospital, Kingsland Road, on Tuesday, March 1st, at 9.30 p.m., when there will be a discussion on headache, in which the following will take part: Dr. H. C. Cuthbert Dixon, Dr. Kendall, Mr. Capps, and Dr. Philip Hamill.

METROPOLITAN COUNTIES BRANCH: NORTH MIDDLESEX DIVISION.—At the meeting of the North Middlesex Division to be held on Wednesday, February 23rd, Mr. Reginald C. Holmes, M.R.C.V.S., will read a paper on "Some diseases of interest to both medical and veterinary professions."

METROPOLITAN COUNTIES BRANCH: SOUTH-WEST ESSEX DIVISION.—A meeting of the South-West Essex Division will be held at Whipps Cross Hospital, Leytonstone, on Tuesday, March 1st, at 3.30 p.m., when Dr. J. C. Muir, medical superintendent of the hospital, will give a clinical demonstration.

METROPOLITAN COUNTIES BRANCH: WESTMINSTER AND HOLBORN DIVISION.—A meeting of the Westminster and Holborn Division will be held on Thursday, February 24th, at 8.45 p.m., at Romano's Restaurant, Strand. Dr. A. Abrahams, Dr. J. Benjafield, Dr. P. Doyne, Major M. Leahy, Mr. H. D. Gillies, Dr. M. Thompson, and other well known medical sportsmen have been invited to take part in a discussion on "Sport, its use and abuse." The meeting will be preceded by dinner at 7.30; the price will be 5s., payable at the table to the honorary secretary, to whom should be sent the names of those intending to be present.

MIDLAND BRANCH: CHESTERFIELD DIVISION.—A meeting of the Chesterfield Division will be held at the Maternity Hospital, Chesterfield, on Friday, February 25th, at 8.15 p.m. Dr. Miles Phillips, professor of midwifery, University of Sheffield, will give an address on "Gynaecological diagnosis."

NORTH OF ENGLAND BRANCH: BISHOP AUCKLAND DIVISION.—A special meeting of the Bishop Auckland Division will be held in the Cottage Hospital, Bishop Auckland, to-day (Friday, February 18th), at 8 p.m. Business: (1) To receive reports from various districts concerning the success or otherwise of collecting arrears accrued during the last coal stoppage; (2) to make arrangements for the annual dinner. The next ordinary monthly meeting will be held in the Cottage Hospital, Bishop Auckland, on Friday, February 25th, at 8 p.m., when Dr. E. Farquhar Murray will give a lecture on "Some modern aspects of obstetrics and gynaecology."

NORTH OF ENGLAND BRANCH: NEWCASTLE-ON-TYNE DIVISION.—Mr. H. S. Elphick, M.R.C.V.S., will give a lecture on March 10th, at 8.30 p.m., in the Library of the Royal Victoria Infirmary, on "Pregnancy and parturition in veterinary practice." The Division is holding a reception and dance with cabaret about the end of March or beginning of April. The arrangements are in the hands of a subcommittee and details will be announced shortly.

NORTH OF ENGLAND BRANCH: SUNDERLAND DIVISION.—A dance in aid of the British Medical Association Charities Fund will be held in Meng's Rooms, Sunderland, on Thursday, March 3rd. Reception by Dr. L. M. H. Ross, chairman of the Sunderland Divison, and Mrs. Ross. Reception, 8 p.m.; dancing, 8.30. Tickets 10s. 6d. Carriages, 1 a.m. Application for tickets should be made to Dr. MacMurray, North Grange, Stockton Road, Sunderland.

OXFORD AND READING BRANCH: WINDSOR DIVISION.—A meeting of the Windsor Division will be held in the Board Room of the King Edward VII Hospital, Windsor, to-day (Friday, February 18th), at 4.15 p.m. Dr. J. J. Paterson, medical officer of health, East Berks United Sanitary Districts, will read a paper on "Poaching, or the relationship of the public health service to private practice." Tea at 4 p.m.

SOUTH WALES AND MONMOUTHSHIRE BRANCH: SWANSEA DIVISION.—A meeting of the Swansea Division will be held at the Hotel Metropole, Swansea, on Thursday, February 24th, at 7 p.m. At 7.15 p.m. Dr. Robert Hutchison will deliver a British Medical Association Lecture entitled "Asthma in childhood." The lecture will be followed by a supper at 8.45 (charge for supper, exclusive of wines, 5s. per head, payable at the table). Members intending to be present are asked to notify one of the honorary secretaries (Dr. H. R. Tighe, 36, Lion Street, Swansea, or Dr. Joseph Lloyd, 66, Walter Road, Swansea) not later than Monday morning, February 21st. Members of other Divisions and their guests will be welcome, provided notification is received by that date. Morning dress. Cars may be left at the Auto Garage Company, Fisher Street.

SURREY BRANCH: CROYDON DIVISION.—A meeting of the Croydon Division will be held at the Croydon General Hospital on Tuesday, February 22nd, at 8.30 p.m., when Professor Leonard Hill, F.R.S., will discuss "Sunshine and open air."

SURREY BRANCH: GUILDFORD DIVISION.—At the meeting of the Guildford Division to be held at the Royal Surrey County Hospital, Guildford, on Thursday, March 3rd, at 4 p.m., there will be a demonstration of cases.

WORCESTER AND HEREFORD BRANCH: HEREFORD DIVISION.—The following programme has been arranged for the year 1927:—March 21st: Ordinary meeting. May 2nd: Annual meeting. July 11th: Meeting to instruct representative. Social meeting in the summer on a date to be arranged. October 3rd: Ordinary meeting. December 5th: Ordinary meeting. It is hoped to arrange a course of post-graduate lectures in the autumn to take the place of a clinical meeting.

YORKSHIRE BRANCH: BRADFORD DIVISION.—On Wednesday, February 23rd, Mr. N. Bishop Harman will deliver a British Medical Association Lecture to the Bradford Division entitled "The recognition of common eye disorders in general practice." The lecture will be given at the Royal Infirmary at 8.30 p.m.

MEDICAL ASSOCIATION OF SOUTH AFRICA (BRITISH MEDICAL ASSOCIATION).

Federal Council.

A MEETING of the Federal Council was held at the British Medical Association Rooms, Wale Street, Capetown, on December 17th and 18th, 1926, with the President, Dr. A. J. ORENSTEIN, in the chair. The attendance numbered fifteen. The following is a brief record of some of the business transacted.

The draft of the Memorandum and Articles of Association, and the agreement with the British Medical Association, were confirmed, and a number of resolutions relating to procedure were adopted.

Among other decisions relating to the newly founded *Journal of the Medical Association of South Africa*, the first issue of which was noticed in the SUPPLEMENT of February 5th, it was resolved that the members of the Federal Council from the Cape (Western) Branch should constitute the Journal Committee, and that the powers of the Federal Council in respect of the *Journal* should be delegated to that committee.

The engagement of Mr. C. L. Leipoldt, F.R.C.S., as Organizing Secretary was confirmed.

The question of acquainting the medical profession of South Africa with the status of health insurance in the principal countries where it is in operation was considered, and it was resolved to inform the Commission on Health Insurance that should it be decided to send a commission to Europe to study this subject, as recommended in the evidence of the Federal Council, the Council considers it essential that this commission shall include one medical man who has had experience in general practice, and also a medical man who has had extensive experience in medical administration. The resolution added that the Federal Council would be very glad to assist in the selection of the general practitioner for this purpose. It was further decided to ask the editors of the *Journal* to devote as much space as possible in forthcoming issues to the exposition of National Health Insurance problems in co-operation with Dr. Charles Porter.

The Council recorded its approval of the principle officially adopted by the British Medical Association in Great Britain, that when any sum is paid by patients, or on their behalf, as hospital fees, a certain proportion of that payment is due to the medical staff which gives the attendance, and the executive was asked to take any steps it thinks fit to promote this view.

In regard to the Medical, Dental, and Pharmacy Bill it was resolved, on the proposal of Sir Edward Thornton, seconded by Dr. Napier, that the Dental Society be invited to appoint two members to the Association's Parliamentary Committee at Capetown, and authority was given for a joint deputation of the medical and dental professions to interview Ministers or other persons to ascertain their views on the advisability of proceeding with the bill.

After full discussion, it was moved by Dr. CHARLES PORTER, seconded by Dr. PEARSON, and agreed, that the Council should express approval of health lectures to the public by whole-time health officers, medical practitioners not in private practice, and also practitioners nominated by Branch councils. It was further agreed that the Executive Committee should consider the provision of lectures to practitioners and to the public by specially appointed lecturers, on the lines of the Canadian scheme.

On the subject of professional charities it was agreed to recommend to Branches that all Branch benevolent funds should be transferred to the Central Benevolent Fund, administered by the Federal Council, and that all balances of Congress funds should be transferred to the Central Benevolent Fund.

Dr. A. WATT brought forward the matter of clinical societies already formed, and in process of formation, in various areas, and it was resolved that the matter be referred to the Executive Committee for consideration and action at an early date.

Meetings of Branches and Divisions.

BIRMINGHAM BRANCH.

THE third ordinary meeting of the Birmingham Branch was held at the Medical Institute, Birmingham, on January 20th, when the president, Dr. H. G. DAIN, was in the chair. Mr. ECCLES SMITH, F.R.C.S., showed three pathological specimens, a volvulus of the caecum and ascending colon, a case of gastric tumour which had been diagnosed by three pathologists variously as linitis plastica, colloid cancer, and polyposis, and thirdly, a specimen showing six gastric ulcers within a small area of the same stomach wall. Dr. DOUGLAS STANLEY read a paper on intrathoracic tumours. He said that the condition was becoming more frequent, and that out of the last 400 odd autopsies at the Queen's Hospital, Birmingham, in 17 pulmonary tumours had been found, and a large number of these were primary growths. He showed specimens and related cases from his own experience to illustrate the various points in the diagnosis and symptomatology of the condition, and he stressed especially the difficulty of diagnosis between acute tuberculosis and malignant disease. A discussion followed, and the meeting closed with a vote of thanks to the lecturer.

BIRMINGHAM BRANCH: NUNEATON AND TAMWORTH DIVISION.

A MEETING of the Nuneaton and Tamworth Division was held at Atherstone on February 2nd. The meeting was arranged by Dr. PRACY, who showed the following cases, skiagrams, and specimens: (1) Patients—(*a*) compound dislocation of the left wrist, with a skiagram, and the bone (scaphoid) which had been removed; (*b*) compound supracondylar fracture of the left humerus, with a skiagram; (*c*) fracture of the tibia only; (*d*) fracture of the radius through the insertion of the pronator radii teres muscle and of the ulna at the same level, with a skiagram; (*e*) unusual foreign body in the tendons of the wrist—the body in question was a piece of glass, which was shown. (2) Two skiagrams were shown of a case of gall stones with carcinoma of the liver, and one of an abscess in the right antrum of Highmore. (3) Slides were displayed of (*a*) tumour from the anus, and (*b*) chronic mastitis with cysts. Dr. Pracy demonstrated the cases and replied to various questions raised during the discussion. A vote of thanks to him for the great trouble he had taken in arranging the meeting and for showing so many interesting cases was carried by acclamation.

DORSET AND WEST HANTS BRANCH: BOURNEMOUTH DIVISION.

A MEETING of the Bournemouth Division was held on February 3rd. In presenting the annual report for the last year the HONORARY SECRETARY said that there had been a net increase of membership of 17, which brought the strength of the Division up to 201. There were seven meetings held during the year, and the average attendance was higher than that of other years.

A motion regarding the adjudication of the General Medical Council in disciplinary cases was discussed and referred to a sub-committee for further consideration and report to a general meeting of the Division at a later date.

DORSET AND WEST HANTS BRANCH: WEST DORSET DIVISION.

A MEETING of the West Dorset Division was held at the County Hospital, Dorchester, on January 27th, at 8 p.m. The attendance was good considering the prevailing epidemic. In the absence

of the chairman, Dr. O. Rees, through ill health, Dr. G. G. MORRICE presided. He showed three cases: (1) Grouped nodular syphilide in a man suffering from acute myelitis. (2) Psoriasiform syphilide in a woman. (3) Dermatitis of foot and leg possibly due to coccal infection. Dr. H. L. NASH-WORTHAM showed specimens of vesical calculi removed from a boy aged 3½, and also a specimen of tuberculous kidneys. Dr. W. RUSSELL read notes on a case on which appendicectomy had been performed and afterwards developed acute dilatation of the stomach; the patient eventually recovered.

Dr. E. W. SMERDON read a paper on "Points in the diagnosis of the acute abdomen." The speaker held his audience throughout this most interesting and valuable paper, which was remarkable both for the amount of matter condensed and the dialectical skill in its rendering.

After a short interval for refreshments the paper and the cases were discussed. Dr. Smerdon was warmly thanked, those present being aware of the fact that Dr. Smerdon had had a most strenuous and fatiguing day.

The honorary secretary was instructed to write to Sir Henry Head, a member of the Division, congratulating him on his recent honour.

LANCASHIRE AND CHESHIRE BRANCH.

Spahlinger Treatment.

At a meeting of the Branch Council of the Lancashire and Cheshire Branch of the British Medical Association, held in Manchester on February 3rd, the following resolutions were passed with regard to the Spahlinger treatment of tuberculosis:

(1) That the Branch Council reaffirms the decision of March 24th, 1925, that a case has been made out for a full investigation of the Spahlinger treatment in England under complete medical supervision.

(2) That under no circumstances does this Branch of the British Medical Association lend its name or reputation to the support of a public appeal for funds in relation to the Spahlinger treatment until such investigation has taken place in England with a successful issue.

NORTH LANCASHIRE AND SOUTH WESTMORLAND BRANCH.

THE annual meeting of the North Lancashire and South Westmorland Branch was held at the Fleece Inn, Kendal, on January 20th, in combination with a Kendal Divisional meeting. Dr. SOMERVELL showed a case of framboesia tropica or yaws. As it was the first case seen at the Branch meeting a good deal of interest was taken in it. The patient was a sea captain; the granuloma was situated in the dorsal region and looked like a mass of granulation tissue; the diagnosis had been verified by the finding of the spirochaete. Professor FLETCHER SHAW (Manchester) delivered an address entitled "Lower abdominal pain in women."

NORTH OF ENGLAND BRANCH: SUNDERLAND DIVISION.

THE annual meeting of the Sunderland Division was held at the Royal Infirmary, Sunderland, on January 25th.

The following officers were elected for the ensuing session:

Chairman, Dr. Z. M. H. Ross. *Vice-Chairman*, Dr. W. B. Milbanke. *Honorary Secretary*, Dr. R. H. Dix. *Representative in Representative Body*, Dr. J. Chalmers. *Charities Secretary*, Dr. J. Chalmers.

A dance will be held in February or March in conjunction, it is hoped, with the West End and Bishopwearmouth East Medical Societies. Further information can be obtained from the convenor of the Dance Subcommittee, Dr. N. F. Rowstron.

The annual report for 1926 was received and approved. It recorded an increase of five in membership, and stated that three business and eight scientific meetings had been held during the year with an average attendance of 26.5 and 24.5 respectively. Thirteen members attended a post-graduate course of lectures on pre-maternity work held in the spring; an attempt to hold a post-graduate course in medicine in the autumn failed for lack of support. The report gave particulars of action taken in connexion with a considerable number of local matters affecting the medical profession.

OXFORD AND READING BRANCH: OXFORD DIVISION.

THE first meeting of the year of the Oxford Division was held at the Radcliffe Infirmary on January 26th, when Dr. WILLIAM COLLIER, sen., was in the chair. Owing to the influenza epidemic the attendance (thirty) was considerably below the average.

Chairman's Speech.

Dr. Collier thanked the Council and members of the Division for the very special honour conferred on him by his election for the second time as its chairman. He expressed his thanks for the support he had received from the members of the Oxford Branch and Oxford Division, extending over a period of forty years. Though the British Medical Association had held three annual meetings at Oxford previous to 1885, it was, he said, only in that year that a Branch was formed, and he took part in the meeting held at the Radcliffe Infirmary in April, 1885, for the purpose. On the resignation in 1897 of Mr. L. Morgan as secretary of the Branch the Council elected him (Dr. Collier) to fill the office. On the reorganization of the Association in 1903 the Oxford Branch was formed into a Division and, with Reading, constituted the Oxford and Reading Branch. The Oxford Division decided to invite the Association to hold its Annual Meeting at Oxford in 1904, and when it was found that the then regius professor of medicine, Sir John Burdon-Sanderson, could not allow himself to be nominated as President on the grounds of health, the Division nominated him (Dr. Collier), and he became President of the Association in 1904. In 1906 he became chairman of the Division. His election to the same office twenty years later made him feel that over a long period of years he had been able to gain and retain the friendship and goodwill of a large number of fellow practitioners, and this he considered a matter of supreme satisfaction.

Clinical Proceedings.

Mr. E. C. BEVERS described an unusual case of a young man who was riding a motor cycle on a country road at dusk and going at a fast rate. The driver of a horse and trap saw him approaching with his head down and shouted to warn him, but in spite of this the cyclist crashed into the trap. He was picked up and was found to be bleeding profusely from a severe wound of the face; although badly shaken he was able shortly to walk a distance of twenty-five yards to a car and was driven to the nearest cottage hospital, whence he was sent on to the Radcliffe Infirmary, Oxford, a distance of some twenty-six miles. On arrival at the hospital he was fully conscious and was supporting his fractured upper jaw with his right hand; there was a severe wound of the face between the eyes, from which blood was running freely; the bones of the nose and both superior maxillae appeared to be comminuted, and a portion of the upper jaw containing eight teeth was separated from the rest. In addition to external bleeding, a good deal of blood appeared to be running down his throat, and from his laboured respiration it was obvious that some had entered the lungs. Within a short time of his admission his breathing became more difficult and stopped; a rapid laryngotomy was done by the house-surgeon, but all efforts to restore respiration failed. Before death it was noticed that there was a projection in his back between the scapulae; this was examined more carefully afterwards and was found to be smooth and rounded and to project beneath the skin to the left of the spine and rather below the spine of the scapula; it was found that on catching hold of this projection and depressing it it was possible to lift up the head, so it was clear that a foreign body had entered the pharynx and had penetrated as far as the skin of the back. At the *post-mortem* examination a large triradiate wound was found over the bridge of the nose; the wound opened into the nasal cavities and both frontal sinuses. The upper jaw was fractured in two places and lay loose underneath the upper lip and lower part of the nose; this portion had eight teeth attached to it. The eyes were unaffected, but the orbital wall on either side was damaged, and in the pharynx was a cylindrical hard body slightly to the left side. Opposite the spine of the left scapula was a bruised portion of skin with a hard knob underneath. On making an incision over this knob there was revealed a brass rounded head which it was only possible to dislodge by hammering and delivering through the facial wound. The track of this foreign body was through the pharynx on the left side, to the left of the spinal column, and about the middle of the cervical region; avoiding the pleura and the big vessels of the neck, it had passed through the muscles of the back to the point above mentioned. The foreign body proved to be the end of the shaft of a trap, 11 inches long and 1½ inches in diameter; it was tipped with brass and had a leather sheath. The accident was an extraordinary one; the rider must have been going at tremendous speed and the impact must have been terrific to drive the blunt end of the shaft through his face, pharynx, and the muscles of his back; also he must have been bending low over his handlebars, as only in this position could the shaft have taken the course it did. It was an interesting fact that the true nature of the injury was not suspected at the time, and the police hunted for the missing end of the shaft without success. It was also remarkable that the cyclist, after such a severe injury, should have been able to walk twenty-five yards and travel a distance of over twenty miles in a car to Oxford sitting upright, as it was impossible for him to lie down, and should have survived the injury over three hours, remaining fully conscious up to the end, which was brought about by aspiration of blood into the lungs.

Dr. J. C. R. FREEBORN showed a form of abdominal rubber and uterine dilator which he had found useful in practice.

Hospital Organization in America.

Mr. HUGH WHITELOCKE gave an account of a recent visit to Canada and the United States, when he observed the present régime in the general hospitals at Montreal, Toronto, Chicago, the Mayo Clinic at Rochester, Cleveland, Baltimore, and Boston. The up-to-date equipment and buildings were everywhere noticeable, especially in the case of private pavilions attached to general hospitals, and of new private hospitals of from 100 to 200 beds, noticeably at Cleveland and Baltimore, where the new Union Memorial Hospital appeared to be the last word in perfection. The vast quantity of material at the Mayo Clinic called for very high degrees of specialization and team work, so that a maximum of work could be observed in a minimum of time. Nevertheless, it was only possible to investigate all departments fully by an intensive inspection lasting nearly three weeks. The surgeons first served as general surgeons, and then each had a specialty. The marked freedom of consultations between surgeons, physicians, and pathologists on all cases was most noticeable, and the clinic largely owed its fame and success to two facts: that no patient was ever allowed to leave with any feeling of dissatisfaction, and that all visitors were shown the utmost courtesy, and every inquiry received the fullest possible explanation and elucidation on all points. Some special features of thyroid, lung, brain, and genito-urinary surgery were briefly detailed.

SIERRA LEONE BRANCH.

THE annual meeting of the Sierra Leone Branch was held on December 30th, 1926. The President, Dr. INNESS, vacated the chair to the President-Elect, Professor BLACKLOCK, who expressed sorrow at the loss of Dr. W. Campbell, a valued member of the Branch, who had died during the year, and the secretary was directed to send a message of condolence to the family. A vote of thanks to the

outgoing officers, especially to the Past-President, Dr. Inness, proposed by the PRESIDENT, was accorded with acclamation. The following officers were elected for the ensuing year:

Vice-President, Dr. Pratt. *President-Elect*, Dr. Peacock. *Honorary Secretary and Treasurer*, Dr. Wright. *Representative in Representative Body, 1927-28*, Dr. Inness. *Deputy Representative*, Dr. Peacock.

The SECRETARY read the financial statement of the Branch, which showed a credit balance of £40 10s. It was resolved that a certain amount of the funds be spent in procuring and printing stationery, and the secretary was asked to prepare and submit forms for the approval of the next meeting. The question of publicity of the Branch was raised by Dr. PEACOCK, who referred especially to the publication of reports of meetings. The question of keeping up-country members informed of the work of the Branch having been considered, it was arranged that after the minutes of future meetings had been provisionally approved by those present at the meeting, a copy should be sent to each member of the Branch.

SOUTH WALES AND MONMOUTHSHIRE BRANCH: SOUTH-WEST WALES DIVISION.

A VERY successful meeting of the South-West Wales Division was held on January 19th at the Carmarthenshire Infirmary, when, despite the pressure due to the influenza epidemic, about twenty members were present to hear a most interesting and instructive address from Mr. T. E. HAMMOND, F.R.C.S. (Cardiff), on "Enlargement of the prostate: its pathology, symptoms, and treatment." Mr. Hammond dealt most lucidly with the various forms of treatment, and gave a lecture which was thoroughly appreciated by all present. Owing to the unavoidable absence of the chairman of the Division, Sir John Lynn-Thomas, Dr. LEWIS WILLIAMS, Ferryside, took the chair, and at the end of the lecture proposed a most hearty vote of thanks to Mr. Hammond for his excellent address. After the meeting all members had tea at the Infirmary.

ULSTER BRANCH: TYRONE DIVISION.

THE inaugural meeting of the Tyrone Division of the British Medical Association was held in the Royal Arms Hotel, Omagh, on January 26th, and an account of the proceedings appeared in the JOURNAL of February 5th (p. 258). Dr. T. HENNESSY, the Irish Medical Secretary, took the chair by invitation and opened the meeting, and after the election of officers Dr. EDWARD THOMPSON, the first chairman of the Division, presided.

On the proposal of Dr. LYLE, seconded by Dr. MCALLISTER, the Model Rules of Organization and revised Ethical Rules governing ethical matters were adopted unanimously. The SECRETARY read a letter from Dr. Malcolm, honorary secretary of the Ulster Branch, regarding the proposal of the Ministry of Labour, Northern Ireland, to appoint part-time referees. As the members present were not convinced that this system did prevail in England and Scotland, and, moreover, understood that the British Medical Association was opposed to part-time referees, the Divisional secretary, Dr. Bradley, was instructed to refer this matter back to the Branch secretary and emphasize the objections expressed. The meeting terminated with a luncheon, the expenses of which were to be borne by the Tyrone Medical Committee.

YORKSHIRE BRANCH: BRADFORD DIVISION.

THE annual dance and supper of the Bradford Division was held at the Midland Hotel, Bradford, on January 27th, at 8 p.m. The chairman, Dr. J. F. Allan, and Mrs. Allan received the guests as they arrived. The room was beautifully decorated with electric lights having various coloured shades, and the effects produced were very pretty. Over one hundred sat down to supper, after which favours were distributed, and these gave an added air of festivity to the scene. Altogether a very enjoyable evening was spent, and the dancers voted the occasion to have been an unqualified success.

BOOKS ADDED TO THE LIBRARY.

THE following books were received by the Library of the Association through the BRITISH MEDICAL JOURNAL during the months of December, 1926, and January, 1927:

Achard, C.: Troubles des Echanges Nutritifs. Two volumes. 1926.
Annals of Medical History. Volume 3, No. 3. September, 1926.
Association for Research in Nervous and Mental Disease. The Human Cerebro-spinal Fluid. 1926.
Belfrage, S. H.: *What's Best to Eat?* 1926.
Berg, L. S.: Nomogenesis or Evolution determined by Law. 1926.
Bombay University Calendar. 1925-27.
Cathcart, G.: Treatment of Chronic Deafness. 1926.
Chandler, A. C.: Animal Parasites. Third edition. 1926.
Chevallier, C. H. [illegible] du Cancer. 1926.
Conybeare, J. J. [illegible]. 1925.
Crowe, H. W.: [illegible]thritis and Rheumatism. 1926.

Correspondence.

The State and the Public Health.

SIR,—You have several times allowed me to argue that the national phthisis mortality depends on the rate of wages (using "wages" to mean "real" wages); that its rise in 1915 was the necessary sequel of a long fall in that rate, beginning from *1896 and coincident with a series of measures* in restraint of production and wages, culminating with the Insurance Act in 1912; that, the respite due to the high wages of the war and immediate post-war period having expired, a rise will follow again within three years, a fact of which the increase of notifications is omen. Will you allow me to point to a strong confirmation of my position which seems to have escaped notice?

In the Registrar-General's Statistical Review we find that at the end of the second decade of this century, except for babies under 1 year, the only age groups which show an increase of vitality are those dating at least from 1895. There is no other decade in our records where improvement in the elder groups is at the expense of the younger. As with consumption, the war when well established checked the retrogression until the epidemic year 1918; and the high wage period immediately following shows a resumption of progress for the time. But there is every sign that at the end of the last quinquennium the processes of 1913 and 1914 are beginning again; and Sir George Newman may well call it a "disappointing and foreboding" fact that the percentage of children entering the schools in class "good" has fallen from 32 in 1915 to about 20 in 1925. Five years is too short a time for dogmatic statement; but it may be suggestive that the further we go from last century the later the age group which shows emphatic progress: in 1920 it was 25; in 1925 it was 35. (The figures for age group 30 are not given.) There is obvious reason why the young should suffer like the consumptive. Both must, so to speak, "sink all their capital in their business," the one of growing, the other of fighting disease, and no large reserve can be accumulated.

Is it not time to recognize a relation between public health and public economy, when coincident with a multiplication by nearly seventeen of the "wretched" State outlay of 1895 is the evidence that it is become a handicap to be born in this century, at any rate in poverty? The dominant policy of the last was concentration on real wages, with ceaseless warning of the costliness to the poor of State gifts, and the inculcation of self-reliance. To the men who have changed all that were bequeathed the highest wage rate on record, a better stock of parents for the race, a number of children's diseases diminished in virulence or range of incidence, a female population of immensely improved vitality, science of treatment and pre-

vention of disease beyond belief advanced. In a quarter of a century they are reimposing on the poor that taint from which the nineteenth century had painfully freed them—a taint which had been imposed by the same meddlesome disregard of economics, if applied from a different angle.

It is more than ever to be regretted that before the Royal Commission on National Health Insurance the British Medical Association did not insist on the discussion of the fundamental principle of the Act, which it shares with so many others. There is the less excuse that it began with the damaging confession that it is "not even probably the best" way to secure national health. Instead of insisting on that best it deliberately spent days and days on tinkering up an instrument whose imperfection of principle it admitted.—I am, etc.,

Bath. B. G. M. BASKETT.

In response to our request for the names of medical men elected to the chairmanship of Insurance Committees a correspondent informs us that on January 28th last, at the annual meeting of the Nottingham Insurance Committee, Dr. J. Holmes Thompson was unanimously elected chairman for the third year in succession.

Naval and Military Appointments.

ROYAL NAVAL MEDICAL SERVICE.

Surgeon Lieutenant Commanders F. H. Vey to the *Alecto*; J. D. Murphy to the *Pembroke* for Chatham Dockyard; F. C. Hunot, W. E. Heath, J. C. Brown, and A. W. McRorie to the *President*, additional for five months' post-graduate course.

Surgeon Lieutenant J. W. Tighe has been promoted to the rank of Surgeon Lieutenant Commander.

Surgeon Lieutenants J. F. Henderson to the *Bee*, additional, and for duty in the *Aphis* and the *Ladybird*; W. G. C. Fitzpatrick to the *Pembroke* for R.N. Hospital, Chatham, temporary.

Bell, assisted by Canon Blofeld), Alfred Birkbeck, M.B., M.R.C.P.Lond., younger son of the late Canon Hodgson of Aston and Mrs. Hodgson of 85, Trinity Road, Birchfields, to Margaret Anne, elder daughter of Mr. and Mrs. Harold Round of "Hill Crest," St. James Road, Edgbaston. At Home "Glencoe," Maney, Sutton Coldfield, March 25th, 26th, and 27th.

JONES—DAVIES.—*On Tuesday*, February 15th, by the Revs. R. Clayton and S. G. Caulton, at St. Dunstan's, William Frederic Jones, M.B., *Ch.B.*, son of Mr. and Mrs. William Jones of Sefton Park, Liverpool, to Mary Elizabeth (late Sister, Bristol Royal Infirmary), daughter of Mr. and Mrs. Davies of Claughton, Cheshire.

WARREN—ARDELL.—On January 1st, at St. Peter's, Kabale, Kigezi, Uganda Protectorate, the Rev. John East Lanfear Warren, *M.C.*, to Kathleen Ardell, M.B., B.S.

DEATHS.

ARCHIBALD.—On January 30th, 1927, suddenly, Robert Richmond Archibald, M.A., M.B., Ch.B., B.Sc., of Woodlands, Denby Dale, Huddersfield, in his 40th year.

DOUGLAS-CRAWFORD.—On February 7th, 1927, very suddenly, Douglas Douglas-Crawford, M.B., C.M.Edin., F.R.C.S.Eng., of 75, Rodney Street, Liverpool.

FEGAN.—On February 9th, in London, Richard [illegible]gan, M.D.St. And., F.R.C.P.I., late of Blackheath and Old Charl[illegible], Kent, and late ex-President, Irish Medical Society, *in his 88th year.* [Funeral, Charlton Cemetery, Friday, February 11th, 2 p.m.]

MITCHELL.—On February 9th, at "Claremont," Chest[illegible]-Street after a long illness, John R. Mitchell, M.B., aged 51 years, late Captain R.A.M.C., formerly of Walker, Newcastle-on-Tyne.

Published by the British Medical Association at their Offices, Tavistock Square, in the Parish of St. Pancras, in the County of London.

Remarks
ON
PRACTICE AND SOME TYPES OF PATIENTS.*

BY
E. B. TURNER, F.R.C.S.,
PAST CHAIRMAN, REPRESENTATIVE BODY, BRITISH MEDICAL ASSOCIATION.

BEFORE proceeding to my subject I shall mention two things which I think are absolutely necessary for you to do—by those of you who are already qualified, now, at once; by those of you who will be taking your first degree in the near future, as soon as you have achieved that honour.

The first of these is that you should at once join one of the medical protection societies. Of late there have been many more actions brought against practitioners for malpractice or neglect than used to be the case. The law courts are open to everybody, and any disgruntled person can bring an action against a doctor whenever he chooses. If you have noticed the results of these recent actions you will have seen that the medical practitioner has generally won his case, but though that may be so, if he were not insured in one of the defence societies his pecuniary loss would have been very heavy, because in many cases the plaintiff is a man of straw and the action speculative, and it is impossible when the case is won to get any costs from him. Moreover, in cases in which some part of the costs may be forthcoming, there is always the balance which has to be paid by the litigant himself—the part of the costs known as that between solicitor and client. If, however, the doctor be a member of one of these societies this liability is taken from his shoulders.

The second is that, as soon as you are registered, you should at once join the British Medical Association. By so doing you will become a member of a great and world-wide association of medical practitioners. You will have opportunities for meeting and coming across most of those of your profession who live in the same district as yourself, and for pulling your weight in whatever movements, political or otherwise, the Association may undertake. You will also receive each week the *British Medical Journal*, which alone is a great asset, and be able to participate in various other material benefits open only to members of the Association. Those who join as soon as they are registered will be admitted at half the usual subscription for a period of years.

*An address (abridged for publication) delivered at a meeting held by the Metropolitan Counties Branch on February 24th for recently qualified practitioners and fourth and fifth year students of medicine.

Final Preparation for Practice.

I am to-day to speak to you on the practice of your profession in whatsoever branch of it you may elect to work, and I think it would be right and proper that I should first say something as to your final preparation for that work in the outside world. To do well in practice a very sound knowledge of your profession, though by far the most important, is by no means the only factor which makes for success. Personality, presence, tact, sympathy, understanding, and a profound knowledge of human nature are indispensable. You cannot begin to cultivate these essentials too early. To do well you must become a "man of parts" in all senses of the word, and all things to all men, and especially all women, for in my own experience I have treated twenty women for every man for whom I have prescribed. Therefore, I urge all of you to have some interests outside your actual profession—cultivate some hobby. I do not care much what it may be so long as it brings you into contact with your fellow men, well away from the bedside, and, if it be possible, into the open air. To some this may not be advisable: your inclinations may lead you to vary your work by taking up another line of scientific research—well and good, "'twill serve," but those of you to whom sport in any form is a real recreation and allurement, "grapple it to your soul with hooks of steel." Do not confine your efforts to one branch of sport only; take up several. Play the strenuous games so long as you may be able, and in later years carry on with those which do not exact so much physical exertion. A sporting reputation will often be of service to you in quite unexpected ways. Do not, however, think I am putting amusement and hobbies in front of real and serious preparation for your future career. A wise student can combine the two. Another thing I wish to impress upon you is this: from now to the end of your professional existence, keep up your anatomy and physiology. These are the twin rocks upon which the whole edifice of your work is founded and built. What is surgery? Even surgery *in excelsis* is but anatomy and common sense, while medicine in addition takes to herself rather more physiology.

I most strongly advise every student to set his face towards house appointments, either in a large teaching hospital, or, if that be not possible, in some other institution. He will be infinitely better qualified for practice if he works as house-physician or house-surgeon with the help and under the supervision of the staff of some hospital. Not only will the experience gained from his cases and the responsibilities he will have to face be invaluable, but if, as I hope it is still the custom, he teaches in the wards as he goes round, that teaching will increase his knowledge and accuracy fourfold.

Special Branches of Practice.

Those of you who have become qualified have reached the culminating point of the first stage of your career as a student of medicine. Students of medicine you are and students of medicine you and every one of us will remain until we cease to function. You will therefore give thought to your future and consider in which branch of the profession you can best employ your talents and abilities. Those who have taken honours, won scholarships and prizes, will naturally turn towards the higher examinations for the M.D. or Fellowship, with a view to an appointment on the staff of a hospital. If you are well qualified and able to give the time and work necessary to obtain and succeed in such a post, you can hardly do better. Some may intend to specialize in some branch of medicine or surgery. If so, be sure that you know your professional work from Alpha to Omega before you confine yourself to study one department only. To be a really competent specialist a man should have a comprehensive knowledge both of medicine and surgery, and if possible should practise some years before starting on his own particular line of work.

We cannot get on without specialists. Some portions of our economy should practically be sacred to them, but when, as has often happened, I have been asked what I know of some eminent gentleman who is supposed to be a specialist for some organ or disease which is so intimately an integral part of medicine and surgery as a whole that every practitioner must have a complete and exhaustive knowledge of it if he is to do any effective work whatever, then it gives me pause to think and wonder.

Some of you may decide to take a commission in the Navy, Army, Air Force, or Indian Medical Service. The authorities of the War Office, working with the British Medical Association, have lately so improved the conditions of service for officers in the R.A.M.C. that anyone will do well to take up that branch of practice should his inclinations lie in that direction.

The Public Health Medical Service and appointments under various Government departments will attract a certain proportion of you. The D.P.H. is now, under the new regulations, more of an honours degree than a mere appendage of letters, and will distinguish those men who intend to devote their life to that which I prefer to call "administrative" medicine. Many attempts have been made to draw a line between clinical and preventive medicine—how far the medical officer of health should go in the treatment of illness, and what should be the duties and the attitude of the clinical practitioner towards the prevention of disease. I am firmly of the opinion that, during the many years I have been giving advice how to avoid illness and how to treat it, I was in fact combining clinical with preventive medicine. Therefore I consider that the terms "clinical" and "administrative" best define the scope of the work of the practising and public health branches of the profession.

In these progressive times there is a magnificent future for the medical officer of health. Though he will often be expected to prevent the unpreventable and remove the irremovable, his opportunities to improve the physical conditions of the people will be abundant, and his influence for good on the health of the community enormous. Every one of you who takes up this particular branch of work on every possible occasion should strive to work hand in glove with the practitioners in your district. Your work will then be far easier of accomplishment and more satisfactory than if a state of armed neutrality or open warfare exist between you and them. One drawback, however, there is to service either under the State or a municipal body. To parody the poet—

"Red Tape is too much with us,
Signing and certifying we lay waste our powers."

Minutes and reports are doubtless necessary to the supervising departments, but I often wonder if equal efficiency could not be secured with half the expenditure of ink, paper, and valuable time, which last, on the part of the doctor, might be so much better employed.

The Work of the General Practitioner.

The greater number of you, however, will go out into the world and start work as general practitioners—in other words, you will take up your position in the front line of defence against the continuous attacks of disease. In London and in the great industrial centres you will be the first to see and appreciate the beginnings and the earliest symptoms of mischief, which in many cases may be of little moment, but in others of the gravest importance. In the sparsely populated rural districts you will be even more responsible. It is hardly possible to overstate the importance of such work, be it undertaken in country or town. In either case your motto must ever be "Principiis obsta," and the early exercise of your intelligence and acumen will save many a life and put a term to years of unnecessary invalidism. However much you may be tempted, never palliate symptoms only—get right down, try to discover the cause of the trouble, and, if possible, remove it. You will have the advantage of seeing your cases when it is possible to benefit them. Your supports, the heavy guns, the consultant and the specialist, often have no chance of doing much good, as they frequently arrive on the scene too late. Therefore, during your preparation for your future practice cultivate without ceasing the ability to make an early and accurate diagnosis, coupled with a sound prognosis, in every case you may see, however commonplace and trivial at the first glance it may appear. You can then take whatever action may be necessary, and when required call up your reserves, and in time.

You are asked to visit a sick person. You will soon find on many occasions that a very urgent summons is dictated by discomfort rather than by danger, while the quiet little note or message—"If you are in this part of the world come and see me some day, I am not feeling very well"—may have behind it a grumbling appendix, the little malignant lump calling out for immediate attention, or the beginnings of some definite disorder. Again, very early in the course of your work you may, you probably will, be confronted with a situation such as you have never had to face during all the years of your training. You may visit a person whom you may never have seen before; apparently on the surface there is very little wrong, but after careful examination you find such unsuspected conditions of disease—hepatic carcinoma, for instance—that a fatal termination is only a matter of a short time. What are you to do, what are you to say? The task is indeed difficult. To combine consideration and mercy to your patient, with justice to his relations and yourself, will call for the exercise of the greatest tact, the most profound sympathy.

You will not see in private practice the same sort of cases that you meet with in hospital. By this I do not mean that pneumonia in a private house differs from pneumonia in a hospital ward; the illness *qua* illness and pathological change is the same; the sufferers may differ, but that is another story. In a great hospital you have gathered together persons afflicted with severe and pronounced disease, the victims of serious accidents and cases which from their very nature and environment are beyond the possibility of proper treatment by the outside practitioner. Therefore you will not see so many grave cases wherever your work may lie. In industrial districts they are more frequent, as the British workman is slow to seek advice unless his ailment is painful or keeps him from work; he seeks aid when his condition approximates to that of the hospital patient. In mining areas you will have to deal frequently with many serious accidents. But if your lot should be to look after the well-fed, well clothed, well housed sections of the community you will be surprised at the small proportion of cases of really serious illness you

will be called upon to attend. I should astonish you if I were to tell you how few cases of tuberculosis of the lungs have been under my care during the last forty-five years. Since I was house-physician at St. George's I have only seen three cases of enteric fever and one of glaucoma.

Some Hints on Private Practice.

Being familiar with all the grave manifestations of disease which you meet in the wards you are able to go with confidence into a house with a sure faith that whatever you may there find cannot be worse than that which you have seen habitually treated in hospital. When seeing a patient always believe in yourself. Do not have an exaggerated self-confidence, but be confident. If you have not confidence in yourself how can you expect a sick person to have confidence in you? Patients are very quick indeed to notice whether a practitioner thinks he is going to do them good or not, and they appreciate confidence almost as much as any other quality in the physician. Again I repeat that house office is invaluable.

Never forget to carry with you into your private practice that habit—the most important of any you may acquire in hospital—of always examining and noting the condition of every organ in every case. You will find that a very large proportion of the mistakes other people make are not due to any lack of knowledge or skill, but to the fact that one or more important organs have not been carefully passed under review.

The work in hospital is done with the aid of every possible appliance—chemical, mechanical, optical, and electrical. Above all things never become slaves to your instruments. Cultivate at all costs that which, wanting a better term, may be called your "*clinical instincts.*" Make the diagnosis with your brains, your eyes, your fingers, and your ears, and then bring in your machinery to confirm or disprove your findings. Of late years I have noticed that many men of the younger generations are very chary of expressing an opinion, even on an obvious case, until they have had the way made plain before them by a laboratory test and instrumental assistance. To use the invaluable methods of modern-day scientific research to this purpose is to degrade them to the function of crutches, the constant use of which will enfeeble your intellectual muscles and doom your independent perceptions to atrophy. Let them rather take the place of a walking-stick that will support your steps in rough places without paralysing your limbs. Times without number you will find the eye, the finger, and the stethoscope, used with a trained clinical intelligence, beat the test tube, the *x* ray, and the swab. Acting on the knowledge thus obtained, you frequently can save much valuable time, to the great benefit of your patient. Use to the very fullest extent, but do not abuse, the assistance given to you by science.

If when you visit a sick person you are fit and well, and (to use a slang expression) "full of beans," you may be certain you will do that individual much more good than if you yourself were feeling depressed and below par. Some persons call this the "gift of healing." Patients are quick indeed to notice your manner and derive confidence and hope, or the reverse, from your demeanour. If you are by nature merry and bright, optimistic and high-spirited, be thankful that you are so constituted, and exercise these powers to the fullest extent. If you are not, assume a cheerfulness though you have it not.

While holding the most exalted ideals of personal and professional honour so far as is possible be all things to all men. A hyperaesthetic enjoying bad health and a bread-winner striving and fretting to get back to his work require quite different management if you are to do your very best for both. To accomplish this requires tact and adaptability. Much good can be done to a patient merely by bringing the life, motion, and fresh air of the outer world into the confined atmosphere of the sick-room. At all times and in all seasons be very gentle with your patient. Take great pains to make an invalid as contented and as comfortable as possible. Let the yoke of your restrictions be as easy and the burden of your directions as light as the exigencies of the case will allow. The bed of sickness is not the bed of Procrustes. You must fit the bed to your patient, not your patient to the bed. Be very explicit in your directions to the patient and his attendants. You would be surprised to hear what I have often found administered as "light simple sort of food." Dot your i's and cross your t's. You will daily have to set out dietary schemes for your patients. Do not fall into the error so common among food reformers and argue from the individual to the mass. It is a certainty that brown bread and vegetables, or beef and beer, will never suit everyone. Study to find out what is best for each particular patient, and "let the punishment fit the crime." The early success of homoeopathy was, in the first instance, a revolt against too much calomel, colocynth, and senna. The drastic drugs which may be the salvation of a navvy are anathema to a thin-skinned, fair-haired, blue-eyed girl. Never prescribe for a person until you have shaken hands with him and thus assured yourself of the texture of his skin and mucous membrane.

Every general practitioner should be prepared to accept and face his own responsibilities. I do not mean by this that an untamed enthusiast should rush in to operate where an expert might well fear to tread, or that a man should be so obsessed by his own opinion of his own skill and importance as to be offended at the idea of a consultation, however difficult and obscure the case may be, but that he should treat, and continue to treat until its conclusion, every illness which comes within his powers. There are always practising men whose repute is greater with the public than with their own profession, who never by any chance take any responsibility whatever if they can avoid it. Should they be confronted with an ordinary conjunctivitis or simple inflamed throat they at once invoke the aid of Sir Adenoid Tonsil or Mr. Cataract Lens and stand by while, under the aegis of these great names, Nature recovers the patient. Such methods, though probably sound enough as regards these particular practitioners, do not conduce either to the good of the patient or to the repute of the profession.

A good physician never treats the illness, but always the patient. Some fifty years ago I attempted to give a strong full-blooded robust country squire in Dorsetshire, suffering from *pneumonia*, the same treatment which I had seen succeed with the poor half-starved denizens of the Embankment and the parks who were admitted into hospital. I was saved from the consequences of my want of experience by an old-fashioned unqualified assistant, and have been ever grateful to him since. Be very friendly with Nature: she is ever striving to heal, and though in her efforts to do so she frequently destroys the individual she means well. Do not rudely obstruct her path—guide, lead, direct her.

Cures, Charlatans, and Cults.

You will but seldom be able to claim that you have cured a person. I am not now speaking of surgical cases: a gangrenous appendix successfully removed is a "cure" and there are even a few specifics in medicine. We aid "recovery," we but seldom "cure."

You will, however, during the whole of your professional life hear of numberless wonderful cures attributed to or accomplished by quacks, herbalists, osteopaths, bonesetters —"Ambubaiarum Collegia, Pharmacopolae hoc genus omne"—unqualified as a rule, though sometimes, I am ashamed to say, a charlatan disgraces a medical degree. You will *hear* of these cures. You will *see* the other side of the picture. When an individual considers himself so far superior to the common herd that the orthodox is not good enough for him, and when either by grace of Nature or in some cases due to the skill and technical competence of the charlatan a good result is obtained, then everyone must hear of it. At all times and in all places he spreads the good tidings, considering his happy fortune a tribute to his own intelligence; and he is ably seconded by the quack, especially if he be a person in the public eye. Like Mr. Vincent Crummles, you may wonder how these things get into the papers, but there they appear, and the whole matter flares up into that glare of publicity and blazon of advertisement which is the very life-blood of the quack but unbecoming conduct on the part of a member of a learned profession. Such are the cases of which you will *hear*. You will *see* the failures. No publicity here; no credit here to quack or quacked. It will be your task to attempt to

repair the damaged joints, to palliate the sufferings, soothe the downward path and sign the death certificates for those who come under your care "cured" of "tuberculosis," or suffering from malignant disease allowed to increase until an operation is neither advisable nor possible. But few hear of these disasters; they sink into oblivion—the oblivion of the sacred confidence between doctor and patient. Be very tolerant in all your dealings with such cases. Even in the present day when insulin, appendicitis, and sterilization of the unfit are discussed at every dinner table, the general public is very unknowing of things medical. "Populus vult decipi et decipiatur."

Very often you will come into contact with the votaries of those cults—religious, semi-religious, psychic, and imaginative—which profess to remove all ills by suggestion and other means of influencing the nervous system. As with quackery, so with these scarcely less harmful fantasies, you will hear only of their virtues. You will experience their vices. But in your haste do not write them all down as pure humbug. Though an abomination to your intellect and intelligence, still, as the small boy said of the lie, you may some time find them a very present help in time of trouble, especially in those very difficult and unsatisfactory cases in which there is nothing whatever the matter with the patient. I mean by this, when he has no organic lesion or definite disease. Great success occasionally attends an attack along these lines in cases of purely functional disorder.

Year by year you will see the rise and follow the decline and fall of many new diseases, of many loudly vaunted methods of treatment, and will regret the premature discussion in public of matters of real scientific interest while yet in the experimental stage. It will be your lot to watch an endless procession of fetishes, each one surviving until pushed out of the limelight by its successor. In the morning they flourish like a green bay tree; in the evening they are cut down dried up and withered.

Relations with Colleagues.

In the course of your future work you are bound to come in contact with your fellow practitioners in many ways and on many occasions. You will hear a great deal about medical etiquette. I want you at once thoroughly to understand that all the rules of medical etiquette have been set forth and are carried out with the one idea and expectation of promoting smooth sympathetic working between practitioners, and thus conducing to the good of the patient. The benefit of the patient in these matters is a supreme law, and when you read and hear about ethical rules you will find that they are always designed to lead up to this good effect. In our profession we are extremely individualistic, and it is certain that there will be occasional friction between us, sometimes even leading to a quarrel. This is always unfortunate and generally unnecessary. If you make a rule to put yourself in the other man's place and act as you think he should act towards you, fighting will be at a discount and ethical rules not required.

There are various canons of behaviour laid down for the members of a learned profession, one of the principal of which is that no improper public advertisement of a particular person should be allowed. The advertisers have always been and always will be with us. A certain number of men do not think that the success to which they themselves consider they are entitled comes to them quickly enough, or having attained a certain notoriety wish to remain in the limelight, and so they take these methods to hurry that success which should come as a result of constant and patient work. This practically means reducing a learned profession to the level of an advertising trade. Doubtless "the jingle of the guinea helps the hurt that honour feels."

You will frequently have to deal with consultants and the ethics of consultation. There are three ways in which most general practitioners regard this subject—two quite wrong, the other right. There is the man I have already mentioned, who is so lacking in confidence that he calls in a consultant to aid him, though in many cases it is quite unnecessary. On the other hand, there is the man who considers that his dignity is affronted and that he is the victim of a deadly insult if the friends and relations of a sick person express a wish for a second opinion. Both attitudes are entirely wrong. The friends and relations of sick people are perfectly entitled, and are often very wise both for the good of the patient and for their own position with the rest of the family, to ask for a second opinion. For my part I am always a little inclined to think that when a man objects very strongly to the aid of any consultant being invoked in his cases that he is really not very sure about his own diagnosis and methods of treatment. The right course is to use the consultant wisely and well. Call him in when you want his advice yourself either to aid you in a difficulty or to share with you the responsibility of a serious case. Call him in at once if you have the slightest reason to think that either your patient or his friends wish it, and as a rule generally be the first to suggest "a second opinion." If possible always adapt your consultant to your patient: it is better for both. One sometimes hears a general practitioner object to consultants because he says they do not strictly regard the rules of medical etiquette, and (to use a slang expression) "pinch" the patients they are asked to see. It is possible that some such cases do occur. Speaking for myself, I have come across perhaps one or two such instances in the last fifty years, and I think that in many cases they are not nearly so blameworthy as they are considered to be. Here I may remark that should you ever hear from a lay person that a doctor has given some extraordinary opinion or stated some impossible fact don't believe it.

The Doctor in Public Life.

If a medical practitioner can find time he should interest himself, and if possible take part, in the public work of his town or district. As members of the Public Health Committee of any municipality two or three unofficial doctors will often be the little leaven which leavens the lump, and their timely influence may turn well meannig but ill informed City Fathers from some action which may gravely affect the health of the community. Every competent practitioner should do whatever in him may lie to educate the public in health matters. Every year health weeks are held all over the country, and films are shown and lectures given under the auspices of the medical officer of health. The doctors of the district should co-operate, and speak to the man and woman in the street, teaching them those things of which they are so ignorant, and which are of such importance. Let me give one hint to those who may do this: be sure your audience can hear you, and then understand you.

What I have said to-day applies to any form of practice in which you may engage; whether it be the practice which has from the beginning been declared by the British Medical Association to be the best and most ideal, that in which you work for the good of your patient, subject only to the common law of the land and the ethics of your own profession, unregulated, uninspected, uncontrolled; or whether, as in the case of many here, it will be your lot to carry on your work on contract or insurance lines. Every word applies both in the letter and spirit to your relations with your patients.

You will not be able to give so much time to each individual case in industrial work as in private general practice, but you can always remember what is due to your patient, and do your work in the highest possible spirit. Aim at the very highest. At the present time the reputation of the medical profession, with the ignorant and unthinking of the public and part of the lay press, does not stand as high as it did some thirteen or fourteen years ago. For this there are various reasons, but it is up to you to do your utmost to restore it to its former prestige among those of the public who are educated and capable of judging.

In whichever branch of your profession you may finally practise you will make lifelong friendships. You will acquire merit when you deserve blame and blame when worthy of praise. These things all come into the day's work, and a philosopher regards them with equanimity.

Ave atque vale.

PROCEEDINGS OF COUNCIL.

Wednesday, February 9th, 1927.

A MEETING of the Council of the Association was held at the Association's House, Tavistock Square, London, on Wednesday, February 9th, 1927. Sir ROBERT BOLAM (Chairman of Council) presided, and the following were the members present:

Mr. R. G. Hogarth (President), Dr. H. B. Brackenbury (Chairman of Representative Body), Mr. N. Bishop Harman (Treasurer), Sir Robert Philip (President-Elect), Dr. C. O. Hawthorne (Deputy Chairman of Representative Body), Dr. G. A. Allan, Dr. J. Barcroft Anderson, Surgeon Rear-Admiral Sir Percy Bassett-Smith, Dr. H. S. Beadles, Sir Alfred Blenkinsop, Dr. J. W. Bone, Dr. H. C. Bristowe, Dr. G. F. Buchan, Dr. J. S. Darling, Dr. C. E. Douglas, Mr. T. P. Dunhill, Mr. W. McAdam Eccles, Dr. D. E. Finlay, Dr. E. R. Fothergill, Dr. D. G. Greenfield, Dr. R. Wallace Henry, Dr. G. B. Hillman, Dr. J. Hudson, Dr. I. W. Johnson, Dr. R. Langdon-Down, Dr. David Lawson, Dr. E. Lewys-Lloyd, Dr. A. Lyndon, Dr. R. A. Lyster, Dr. J. G. McCutcheon, Dr. S. Morton Mackenzie, Dr. A. Manknell, Dr. O. Marriott, Dr. J. C. Matthews, Dr. G. W. Miller, Dr. Hugh Miller, Dr. Christine Murrell, Mr. A. W. Nuthall, Dr. W. Paterson, Dr. J. Dodds Price, Dr. F. Radcliffe, Dr. Lockhart Stephens, Dr. John Stevens, Dr. W. E. Thomas, Dr. G. Clark Trotter, Sir Jenner Verrall, and Dr. J. F. Walker.

Apologies for absence were received from Dr. F. G. Thomson, Dr. H. G. Dain, Dr. F. J. Gomez, Dr. E. K. Le Fleming, Dr. R. W. Leslie, Sir Richard Luce, M.P., Dr. J. A. Macdonald, Dr. John Mills, Lieut.-Colonel F. O'Kinealy, Group Captain N. J. Roche, Mr. H. S. Souttar, Mr. E. B. Turner, Dr. D. Walshe, and Sir William de Courcy Wheeler.

Personal.

The Chairman said that the members would have learned with much sorrow that since the last meeting of the Council Dr. Ridley Bailey had passed away. They knew that he was comforted in his last and severe illness by the sympathy he received, conveyed by letters and visits, from his colleagues in the work of the Association. The profession had lost a most admirable leader in the Staffordshire district, and the Council and its committees an assiduous member, and one whose personality was greatly appreciated. Three former members of Council had also passed away—namely, Dr. T. R. Bradshaw (1905-9), Sir Isambard Owen (1899-1900), and Dr. F. O. Stedman (1904-6 and 1920-22). The Council stood for a few moments in silence.

The congratulations of the Council were conveyed to Sir Henry Head and Sir Thomas Houston, members of the Association, on the honour of knighthood recently conferred upon them; also to Lieut.-General Sir John Goodwin upon his appointment as Governor of Queensland. It was reported that the President had sent a cable conveying the good wishes of the Association to the Australasian Medical Congress which was meeting at Dunedin, also a telegram of congratulation to Dr. J. Moore Swain, Long Clawson, Melton Mowbray, on the attainment of his hundredth birthday in January; Dr. Swain was a member of the Association for nearly forty years.

Other Preliminary Business.

It was agreed to accede to a request from the Council of the Poor Law Medical Officers' Association that that body should be allowed to nominate a representative upon the special committee appointed by the Council to consider the report of the Royal Commission on National Health Insurance in regard to extension of the scope of medical benefit. It was also resolved for the present year to continue the appointment of Dr. Brackenbury as the representative of the Association upon the Council of the Faculty of Insurance.

The Ministry of Health had been informed, on behalf of the Association, that it was desirable that the Mental Deficiency Bill, which passed through the House of Lords in 1926, and was carried through various stages in the House of Commons, but eventually dropped by the Government, should be re-introduced at an early stage of the present session.

It was reported that at a meeting of the directors of the Scholastic, Clerical, and Medical Association, Ltd., Sir Robert Bolam, Mr. Bishop Harman, and Dr. Morton Mackenzie had been elected to fill the three existing vacancies on the board of directors.

Pharmacists in the Army.

Sir Percy Bassett-Smith (in the absence of Sir Richard Luce owing to illness), in submitting the report of the Naval and Military Committee, drew attention to the question of the employment of qualified pharmacists in the army. A deputation from the League of Ex-service Pharmacists in connexion with the Pharmaceutical Society had been received by the committee, and had asked for support for its efforts to secure the employment of qualified pharmacists by the military authorities. At present the dispensing of medicines, even those containing dangerous drugs and poisons, in military hospitals was carried out by non-commissioned officers and men of the R.A.M.C. who did not possess a pharmacist's qualifications, whereas in the large naval hospitals pharmacists were employed. Sir Percy said that the committee had come to the conclusion that the request was a reasonable one, and it brought forward accordingly a recommendation that the Council should express itself in favour of the efforts of the league in question to secure that qualified pharmacists should be employed in the larger military hospitals. Dr. Bone thought that the recommendation required rather more careful framing in view of the evidence to be given by the Association to the Committee on the Poisons and Pharmacy Acts, which would come before the Council at a later stage that day, and which dealt in specific terms with the qualifications of dispensers in hospitals generally. The recommendation, however, was agreed to as it stood.

Scale of Salaries of Medical Officers in Scotland.

Dr. Hugh Miller, chairman of the Scottish Committee, reported that negotiations were proceeding with the Scottish Board of Health regarding the proposed modifications of the scale of salaries for medical officers employed by local authorities. There were one or two outstanding points not yet satisfactorily disposed of, but in the main an agreement had been reached, and he hoped it would be possible to report to the next meeting of the Council that the Board of Health had accepted the proposed scale as modified.

Spa Treatment for Insured Persons.

Dr. Brackenbury (in the absence of Dr. Dain, chairman of the committee, owing to illness) brought forward the report of the Insurance Acts Committee, and drew attention particularly to the question of spa treatment for insured persons, on which he thought it would be necessary for the Council to take some action. Negotiations had been going on between the spa authorities and other bodies interested in the question and certain approved societies with a view to the provision of spa treatment as an additional benefit. The Insurance Acts Committee decided that if a request were made it would send representatives to a conference which, it was understood, was likely to be called to consider a scheme. Since then, however, the British Committee on Rheumatism had accepted an offer which appeared to have been informally made to it by Dr. Fothergill, who represented the Insurance Acts Committee on that body, that the Association itself should summon a conference on the subject. Those who were aware of what was going on in relation to this matter would feel that it was extremely desirable that such a conference should be called under the auspices of the Insurance Acts Committee or of the Council.

Dr. Fothergill said that he was placed on the British committee of this international body to represent the Insurance Acts Committee, and at the first meeting he was rather alarmed at the way in which approved societies and others concerned with insurance organization were drafting schemes and coming to conclusions with regard to insured persons without consulting those who knew anything about the medical side of national

insurance. A scheme for spa treatment affecting insured persons in London was proposed, and he thereupon suggested that a conference on the subject should be called, and that the Association was the appropriate body to call it. This offer was supported by the medical men on the committee, and eventually was accepted. He thought the Council would do well to call the conference and allow it to elaborate its proposals, such proposals to be sent to the Council and to the other bodies concerned.

The Medical Secretary said that, owing to the useful intervention of Dr. Fothergill, an official request had been received from the British Committee on Rheumatism, which was a very influential body, that the Association should summon this conference. The conference would consist of representatives of spa doctors, of mineral water hospitals, of spas, approved societies, and insurance practitioners. Three representatives of the Insurance Acts Committee had already been nominated before it was known that the conference would be summoned by the Association, but he thought there should be representatives of the general interests of practitioners. This was a real opportunity to assert the authority, influence, and usefulness of the Association.

Dr. Brackenbury said that the suggested reference was the provision of spa treatment for insured rheumatic patients, with special reference to the relationship between spa practitioners and insurance practitioners. He moved that such a conference be called by the Association, and this was agreed to.

At a later stage it was resolved that the following bodies be invited to send representatives: The Spa Practitioners' Association, the lay authorities of the mineral water hospitals, the approved societies, the British Spa Federation, and the British Committee on Rheumatism; and that the following be appointed to represent the British Medical Association (the latter three of whom had already been nominated by the Insurance Acts Committee): Dr. F. G. Thomson, Dr. A. Manknell, Dr. C. O. Hawthorne, Dr. H. G. Dain, Dr. E. R. Fothergill, and Mr. Lewis Lilley. Power was given to the British Medical Association representatives to issue invitations to other bodies should they consider it necessary.

Charities.

Dr. Walker, in submitting the report of the Charities Committee, reported that during 1926 the subscriptions and donations collected amounted to £3,259, a substantial increase on the previous year, though he was not able to say what proportion of this sum represented new money. The amount had been distributed as follows:

	£
Royal Medical Benevolent Fund	1,641
Royal Medical Foundation of Epsom College ...	1,241
Royal Medical Benevolent Fund Society of Ireland	85
Sir Charles Hastings Fund	142
Royal Medical Benevolent Fund Guild	150

In each case, except the last, the amount included certain ear-marked contributions, as well as an allocation from the Association Charities Fund. Dr. Walker also submitted a draft letter on the objects and uses of the Charities Trust Fund, which was being sent out to the chairmen, secretaries, and charities secretaries of Divisions.

Jenner's House.

The Chairman stated that an interesting offer had been made to the Association by Lord Berkeley to present Phipps Cottage at Berkeley, where Dr. Edward Jenner vaccinated the historic patient Phipps, to the Association, for the purpose of establishing a Jenner memorial museum. The difficulty was, however, that the Wellcome Historical Medical Museum already had an extensive collection of Jenner relics, and that a second collection of any real worth would be almost impossible to establish. The authorities of the Wellcome Museum did not see their way to fall in with the suggestion to transfer the whole or part of their collection to Phipps Cottage, and in these circumstances he thought it would be unwise for the Association to take the responsibility of establishing such a museum. He had himself gone down to Berkeley and seen the cottage, and had interviewed the agent, as well as representatives of the Wellcome Museum; the contention of the latter was that the Jenner relics should be in a central situation such as their museum offered.

The Council expressed its cordial thanks to Lord Berkeley for his offer, and its regret that, for the reasons just stated, the offer should have to be declined.

A Legal Actions Committee.

A good deal of time was taken, on the report of the Office Committee, in discussing the question of office procedure in the case of possible legal actions commenced by or against the Association. The Office Committee proposed that a committee should be set up which could be consulted promptly by the officials in the event of any threatened action or of possible necessity for the Association itself to institute action. This committee would also be available for consultation at any time on the conduct of a case. It was proposed that it should consist of the principal officers of the Association, the chairmen of the Journal and Ethical Committees, with the Editor, Medical Secretary, and Financial Secretary.

Dr. Fothergill raised the question as to whether the committee could rightly be authorized to commence an action or to act otherwise than in emergency without consultation with the Council. Dr. Douglas also deprecated power being given to any committee to take the initiative without such consultation. Dr. Langdon-Down pointed out, however, that even in actions which the Association itself brought, everything depended upon promptness, and if, for example, a statement thought to be libellous was published against the Association and the Association awaited a meeting of Council before taking action, it would be held that the force of the indignation must have spent itself, and that the Association was not serious when it was so tardy in taking action. The Chairman said that somebody in such cases had to take the responsibility of instructing the Solicitor. It was impracticable to await a meeting of Council and take its decision, but the responsibility should be thrust upon the largest practicable body which could be rapidly summoned, and which would have the authority of the Council to take emergency action.

After further discussion it was agreed that the Legal Actions Committee be appointed, and that the question of the admission of officials of the Association as voting members or simply as advisers be further considered and brought up at the next meeting.

The Autumn Dinner.

The Council discussed the question of holding another Autumn Dinner in the Great Hall. The last dinner was not well attended, though in other respects it was most successful; the cost of catering in the Great Hall was very much greater than in an hotel. Dr. Morton Mackenzie pointed out the value to the Association of giving such a dinner in its own beautiful house; it was a very pleasant variant from the ordinary hotel dinner to which Ministers and other prominent guests were accustomed. Dr. Fothergill suggested following the example of the Literary Fund Dinner and making it an occasion to assist the Charities Fund of the Association. Another suggestion was that a conversazione be substituted. It was agreed, with three dissentients, that the Autumn Dinner be held in 1927, but that it take place in an hotel and not in the Great Hall.

The Association's Building.

The Council devoted almost two hours to a discussion of a private report by the Building Committee on the development of the space in front of the present building when possession is obtained of certain of the houses whose leases are falling in. The Chairman made a long statement on the position, and in the ensuing discussion the following took part: Sir Jenner Verrall, Dr. Johnson, Dr. Lawson, Dr. Douglas, Dr. Fothergill, Dr. Radcliffe, Dr. Barcroft Anderson, Mr. Bishop Harman, Dr. Beadles, Dr. Morton Mackenzie, Dr. Clark Trotter, Dr. Stevens, Dr. McCutcheon, and Dr. Brackenbury. The Chairman then replied to various questions raised. It was agreed that an architect be asked to prepare such rough sketch plans and elevations as would enable the Council to envisage the extension of the building, and upon which a builder could estimate the approximate cost. A further motion was agreed to empowering the Building Committee, should the figures so obtained be satisfactory, to proceed with certain negotiations with the Bedford Estate Trust.

Tests for Drunkenness.

Dr. Wallace Henry, on behalf of the Committee on Tests for Drunkenness, submitted the report which appeared in last

week's SUPPLEMENT (pp. 53-58). He regretted that Sir William Macpherson, the chairman of the committee, was not now a member of the Council and able to present the report in person. It was only due to Sir William's great patience that anything like order had at last been produced out of chaos. Members would recollect the origin of this committee. Some two or three years ago there was a good deal of anxiety on the part of the public in view of the different procedures followed in dealing with charges of drunkenness brought before the courts, and the question arose whether the tests commonly employed were adequate. The metropolitan police surgeons proposed to hold an inquiry, but afterwards approached the Council with a view to setting on foot a more extended and complete investigation. With regard to the committee's definition of "drunk"—"that the person concerned was so much under the influence of alcohol as to have lost control of his faculties to such an extent as to render him unable to execute safely the occupation on which he was engaged at the material time"—it was noteworthy that only three or four weeks ago, before this report was available, one of H.M. judges had used almost those very words in dealing with a case in which the question of drunkenness arose. Dr. Henry summarized the classification of the tests, emphasizing the finding that no single test, taken by itself, would justify a practitioner in deciding that the amount of alcohol consumed had caused a person to lose control of his faculties; the decision must be based on a combination of tests. The report was the result of general agreement on the part of the committee, and every member signed it. He moved that it be submitted by the Council to the Annual Representative Meeting as the report of a committee of the Association on a matter of public interest. He pointed out that this did not bind the Council to agreement with every word of the report.

Dr. Douglas asked whether the Council was bound by this report to regard the definition of drunkenness therein contained as the best possible one. If so, he was bound to criticize it. Dr. Henry said that the definition was only arrived at after about four meetings of the committee. There was at first an intense divergence of opinion as to how drunkenness should be defined, and he thought it would be very undesirable now to alter the careful wording, which was really a compromise.

Mr. Bishop Harman recalled that at the meeting of the Marylebone Division held two years ago to consider tests for drunkenness the failure of convergence of the eyes was proclaimed by a police surgeon as a decisive test. He was glad to have it now described as one of those tests on which, taken by itself, little stress should be laid.

The recommendation was agreed to, and it was also agreed to authorize the report to be published and put on sale without delay. The thanks of the Council were conveyed to Sir William Macpherson and his colleagues for the labours they had expended upon this subject.

Constitution of the Association.

On the report of the Organization Committee a discussion arose as to the conditions under which resolutions of the Representative Body became the policy of the Association. The Committee's view was that any proposal for enunciation of policy upon which the Representative Body had not previously expressed an opinion must require two months' notice. The article and by-law dealing with this matter, however, were not as clear as they should be, and the Organization Committee had noted their phraseology for revision when changes in the articles were contemplated. Dr. Fothergill hoped the Council would forthwith take up the question of interpretation. He urged that if the Representative Body met to discuss a problem and two-thirds of those present decided in a particular way such a decision constituted a valid enunciation of policy irrespective of the length of notice given. Dr. Brackenbury pointed out that there were three phrases in common use—"the policy of the Association," "a decision of the Association," and "a resolution of the Representative Body"—and they all meant different things. The "policy of the Association," when these words were used in the by-laws, meant the whole body of doctrine which the Association had set forth in certain resolutions, and any addition was an alteration of policy, and should require not only the two-thirds majority but the two months' notice.

The revision of the phraseology was left for subsequent consideration.

Dr. Morton Mackenzie had the pleasure of reporting that the Federal Council of the Medical Association of South Africa (British Medical Association) had accepted the home Council's amendments to the draft memorandum and articles of association, and everything had gone through in the most harmonious and satisfactory manner.

A memorandum by the Medical Secretary was submitted suggesting how the machinery of the Association might be adapted to secure that certain comparatively small and widely scattered sections of members, such as pathologists, engaged in special spheres of professional work, had their views represented and their interests protected. Dr. Mackenzie hoped to submit to the next meeting of Council a draft scheme giving effect to the suggestions.

Dr. Lyndon, as chairman of the Ethical Committee, brought forward a proposal that Divisions be advised, when discussing any important point of policy, to preface resolutions with the words, "That it be recommended to the Council"—or to the Representative Body, as the case might be. The matter arose in connexion with the resolution on education of the public in health, taken at a recent meeting of the St. Pancras Division addressed by Sir Thomas Horder, which resolution was regarded by the lay press as the considered policy of the Association. Dr. Beadles pointed out that the resolution in question was not one passed at a Divisional meeting, but at a meeting to which members of the profession in general were invited. The question was taken back for further consideration.

Charges against Members.

The Ethical Committee also brought forward the question of the position of the Association in the case of a member against whom a criminal offence or a charge of infamous conduct in a professional respect was alleged. This arose on a communication from the New South Wales Branch, which had sought the opinion of counsel (Sir E. M. Mitchell, K.C.). Counsel's opinion was that the Branch council was entitled, in a case of criminal conduct by a member coming within its knowledge, to report to the Crown law authorities, or, in the case of infamous conduct in a professional respect, to the Medical Board—the equivalent of the General Medical Council. On the Branch inquiring as to the views of the home Council, the Ethical Committee also sought the opinion of counsel (Mr. Stuart Bevan, K.C.), which was to the effect that in a case of criminal conduct the Council was within its legal rights in reporting to the authorities, and that it was its duty so to report. In a case of infamous conduct in a professional respect, short of a crime, the Council was also within its strict legal rights in communicating with the General Medical Council, but as the Council of the Association was itself invested with wide powers of inquiry it seemed to counsel that what might be called the public or moral or social duty in this instance would be fully discharged by the Council itself; if the result of the inquiry was the expulsion of the member, the Council of the Association could then communicate with the General Medical Council. It seemed to him that besides the duty which it owed to the public, the Council of the Association had its duty to the members, including the member complained of, to institute the inquiry to which by the terms of membership the members had agreed to submit.

Dr. Lyndon said the Council had always set itself against acting as detective, and had not instituted proceedings against a member before the General Medical Council, believing that the Association might be restrained by injunction from employing funds, to which the member had contributed, against himself, and also that in going before the General Medical Council the Association would be in the anomalous position of having taken no steps to remove from its own membership one who by implication was held to be deserving of removal from the *Medical Register*.

Dr. Beadles said that, in view of what he understood to be the opinion of a solicitor in a recent case, he was distinctly pleased to have the opinion of Mr. Bevan that it would be the duty of the Association first to expel a member before prosecuting him before the General Medical Council.

Hospital Policy.

Mr. McAdam Eccles (in the absence through illness of Mr. Souttar, chairman of the Hospitals Committee) brought forward

a report the principal matter in which was the position of the voluntary hospitals with regard to the recovery of money from patients, particularly in the case of persons brought into hospital after street accidents. The Hospitals Committee thought it advisable to obtain counsel's opinion as to the legal position of hospitals in this respect, and the Council agreed.

The proposal was also brought forward from the Hospitals Committee that certain paragraphs in the Hospital Policy (34 and 36), having served their purpose in introducing the recognition of the services of visiting medical staffs of hospitals, should be deleted, and a new paragraph inserted as follows:

> The visiting medical staffs of hospitals should seek to secure arrangements with boards of hospitals for the satisfactory recognition of their services in accordance with the preceding paragraphs of this section in regard to patients by whom or for whom payments are made to the hospital. Any laxity in securing such recognition is detrimental to medical work of all kinds and ultimately to the general public.

After a brief discussion this recommendation was taken back for further consideration; meanwhile the Council agreed to the deletion of the existing paragraphs.

Mr. Eccles reported, with regard to the matter of the British Hertford Hospital, Paris, that he understood that the Government was prepared to act in the manner suggested by the Association and appoint an independent and impartial arbitrator (not a medical man) to consider the whole of the evidence and decide whether the committee of the hospital had done the late resident medical officer an injustice in dismissing him. The Hospitals Committee had appointed a subcommittee to negotiate as to the terms of reference to the arbitrator.

Exemption of Dogs from Experimental Research.

Dr. Hawthorne proposed the following resolution:

> That in the event of any active parliamentary or extra-parliamentary agitation in favour of a bill to exempt dogs from the provisions of the Vivisection Act, the Science Committee be authorized to take such steps as may seem to be advisable to organize medical opposition to a proposal which, by interfering with the advance of scientific knowledge, must, if adopted, be prejudicial to the public welfare.

He said that this was a motion which arose out of a new controversy on vivisection. It was common knowledge that there were members of the community who objected altogether to experiments on animals, and there were others who limited their objection to the use of dogs for this purpose. Bills had been introduced on former occasions in one or other House of Parliament for the exemption of dogs, but had not been successful. During the present session there was likely to be a special effort made to carry a Dogs Protection Bill, and a new fact which might lend force to the proposal was that, while hitherto the Society for the Prevention of Cruelty to Animals had maintained a neutral position, a resolution in support of such a bill had recently been carried in its council. As a matter of fact, the contingency which was contemplated when this motion was drafted had arrived, and a vigorous effort was being made throughout the country to get a petition signed on an extensive scale and presented to Parliament in support of a bill. The Association had on previous occasions taken the steps he now proposed, and had prepared memorandums on the subject. Recently the Science Committee, under the guidance of two of its members, had prepared a memorandum, which was published in the BRITISH MEDICAL JOURNAL, on the need for the use of dogs in physiological and therapeutic experiments (December 4th, 1926, p. 1073). They had been urged to take action from two different sources—on the one hand from experts who were engaged in these researches, and who stated that their work would be paralysed if the Dogs Bill became law, and on the other hand from the Research Defence Society. Certain members of Parliament could be counted on to put up opposition to such a bill, but they had to be provided with ammunition, and, as far as possible, with the moral support which came from a united profession. Dr. Hawthorne added that there existed already on the statute book a Dogs Act, which must be carefully distinguished from the proposed legislation. The Dogs Act dealt with what were technically called stray dogs. Such dogs were taken charge of by the police and an endeavour made to discover their owners. If the owner was not forthcoming within a certain number of days the dog had to be sold or destroyed, and every year in the metropolis 50,000 dogs were destroyed in accordance with this measure. They could not be used for the purpose of experiment.

The motion was carried.

The Poisons and Pharmacy Acts.

A précis of the evidence to be given by the witnesses for the Association (Dr. Bone, Dr. Lewis Lilley, and the Medical Secretary) before the Committee on the Poisons and Pharmacy Acts was submitted.

Dr. Hawthorne took exception to certain points in the evidence. He noticed that although it was recommended that the name of the poison should be stated on the label, nothing was said about putting thereon the word "Poison" itself. He thought also that some proposal should be made with regard to containers, otherwise the poison might be sold in vessels similar to those employed in the sale of foods and drinks. But his chief exception was to a statement with regard to the qualifications of dispensers in hospitals. The evidence appeared to suggest that the qualification granted by the Pharmaceutical Society and the assistant's certificate for dispensing granted by the Apothecaries' Hall were equivalent. He pointed out various respects in which the two qualifications differed. The qualification of the Pharmaceutical Society was only given after various stringent conditions as to training had been fulfilled, and it conferred the legal right to keep open an establishment for the sale and dispensing of poisons; whereas the assistant's diploma for dispensing of the Apothecaries' Hall was really only intended to permit of dispensing by its holder under the supervision of some competent person.

Dr. Bone quite agreed that the word "Poison" should be placed on the label as well as the name of the poison, also as to the form of the container. With regard to the qualifications of dispensers, it had to be remembered that at present a good deal of institutional dispensing was done by those who had no qualifications at all, and it was thought to be rather "stiff" to require all institutions, no matter how small, to have a qualified pharmacist. The institutions in view would include quite small hospitals and sanatoriums, where the dispenser was practically only a bottler. In the case of the larger hospitals he agreed with Dr. Hawthorne's contention.

The Chairman said that he thought Dr. Bone had gathered the sense of the Council, and would be able to amplify the written by oral evidence making clear the exact position.

The Council concluded, at 7 p.m., a session which had lasted from 10 a.m.

British Medical Association.

CURRENT NOTES.

The Edinburgh Meeting: Hotel Accommodation.

THE Hotels and Lodgings Committee has practically completed its arrangements for coping with the large numbers who are expected to visit Edinburgh in July. In order to secure the accommodation which is believed to be necessary, the Committee has definitely engaged all the available rooms in the city, and will allocate these to applicants in rotation. The Scottish Medical Secretary (Dr. Drever) has undertaken to do this work for the Committee, and applications for rooms should be sent to him at 6, Drumsheugh Gardens. A form for the purpose has been prepared for the convenience of members and will be found on advertisement page 6 of this issue; it will be repeated in subsequent issues. The accommodation is grouped in three classes—namely:

1. Hotels, whose tariff for bed and breakfast ranges between 8s. 6d. and 14s. The number who can be accommodated in these is comparatively limited.

2. Private hotels and boarding houses, at prices from 5s. 6d. to 8s. 6d. for bed and breakfast. Of these there is a large number, all of them comfortable.

3. Hostels where the tariff is 8s. for bed and breakfast. Not many of these are available, but those that are can be recommended.

Garage accommodation has also been secured, and lodgings for chauffeurs.

It will facilitate other arrangements if members who

intend to be present at the Annual Meeting will notify their intention whether they have already secured rooms or not. Early application for rooms is earnestly desired.

Subscriptions for 1927.

The application for payment of subscriptions for 1927 met with an overwhelming response in the first two or three days of this year. More than 10,000 cheques (representing about one-third of the members of the Association) were received within the first week, and for this response the Finance Department desires to express sincere thanks; but there are still many members of the Association who have not yet forwarded their subscription for the current year, and the additional cost of preparing and posting reminders to those whose subscriptions are still outstanding involves each year a large sum which could be better employed in the Association's interest. An earnest appeal is therefore made to those who have not already remitted, to send their subscription for 1927 before the end of this month, adding thereto such sums for the charities or the other funds mentioned on the application form as their instincts prompt and their means will allow.

Association Notices.

ELECTION OF MEMBERS OF COUNCIL BY BRANCHES OUTSIDE THE UNITED KINGDOM.

THE following being the only nominations received for the election of the Council for 1927-28 (or the longer periods indicated) by Branches outside the United Kingdom, the practitioners in question are hereby declared duly elected Members of the Council for the periods mentioned:

Mr. T. P. DUNHILL, C.M.G. (*for the year 1927-28*), New South Wales and Queensland Branches.

Sir JENNER VERRALL, LL.D. (*for the year 1927-28*), South Australian, Tasmanian, Victorian, and West Australian Branches.

Dr. F. J. GOMEZ (*for the three years 1927-30*), Barbados, Bermuda, British Guiana, Grenada, Jamaica, Leeward Islands, St. Lucia, and Trinidad and Tobago Branches.

Lieut.-Colonel ASHTON STREET, F.R.C.S., I.M.S.(ret.) (*for the three years 1927-30*), Assam, Baluchistan, Bombay, Burma, Ceylon, Hyderabad, Mesopotamia, Northern Bengal, Punjab, and South Indian and Madras Branches.

Dr. O. MARRIOTT (*for the year 1927-28*), Hong-Kong and China, and Malaya Branches.

The following is the position as regards the other Groups of Branches outside the United Kingdom:

Dr. J. BARCROFT ANDERSON (*was elected for the three years 1925-28*), African Group of Branches.

Dr. G. CLARK TROTTER (*for 1926-28*), New Zealand and Fiji Branches.

RUGBY DIVISION.

NOTICE is hereby given to all concerned of the formation by the Council of the Association of a Rugby Division of the Birmingham Branch, of area as follows:

The urban district of Rugby;

The rural districts of Rugby and Monk's Kirby;

the new Division to come into existence as from the date of publication of this Notice, and the area of the Warwick and Leamington Division being modified accordingly.

February 26th, 1927. ALFRED COX, *Medical Secretary.*

BRANCH AND DIVISION MEETINGS TO BE HELD.

BIRMINGHAM BRANCH: COVENTRY DIVISION.—At the meeting of the Coventry Division to be held on Tuesday, March 1st, Dr. A. T. W. Forrester will read a paper on "The diagnosis and treatment of early mental cases."

BIRMINGHAM BRANCH: NUNEATON AND TAMWORTH DIVISION.—A meeting of the Nuneaton and Tamworth Division will be held at the Tamworth General Hospital on Thursday, March 3rd, at 3.30 p.m., when Mr. A. B. Danby, F.R.C.S., will read a paper entitled "The role of prevention in obstetrics."

DORSET AND WEST HANTS BRANCH: BOURNEMOUTH DIVISION.—The annual dinner of the Bournemouth Division will be held on Thursday, March 3rd, at the Royal Bath Hotel, at 7.30 p.m. for 7.45. It is hoped that as many members as possible will come and bring guests, including ladies, with them. Tickets, 8s. 6d. each (exclusive of wine). Application for tickets, together with remittance, must be made by Monday, February 28th.

GLASGOW AND WEST OF SCOTLAND BRANCH: DUMBARTONSHIRE DIVISION.—A dinner of members of the Dumbartonshire Division will be held in the North British Station Hotel, Queen Street, Glasgow, on Wednesday, March 9th, at 7.30 p.m., when Dr. W. B. Armstrong (Lenzie) will take the chair. Tickets 15s., payable in advance or at the dinner. Members are asked to notify the honorary secretary, Dr. T. Miller, Netherton, Dumbarton, before March 2nd, if they intend to be present and if they are bringing a medical guest.

METROPOLITAN COUNTIES BRANCH: CITY DIVISION.—A meeting of the City Division will be held at the Metropolitan Hospital, Kingsland Road, on Tuesday, March 1st, at 9.30 p.m., when there will be a discussion on headache, in which the following will take part: Dr. H. C. Cuthbert Dixon, Dr. Kendall, Mr. Capps, and Dr. Philip Hamill. The annual fancy dress dance will be held on Thursday, March 24th, in the Great Hall of the British Medical Association Headquarters, Tavistock Square. It is hoped that members will make up parties. First class band, and refreshments by Gunters, Ltd. Dancing, 8.30 p.m. to 1.30 a.m. Ticket, inclusive price 8s. Cars may be garaged in the Association garage. Tickets may be obtained from Dr. Harold Latham, 2, Hemingford Road, Barnsbury; Dr. G. Clark Trotter, 2, Tyndale Place, Upper Street, Islington; and from the honorary secretary, Dr. Worley, 43, De Beauvoir Road, N.1.

METROPOLITAN COUNTIES BRANCH: ST. PANCRAS DIVISION.—A meeting of the St. Pancras Division will be held in the British Medical Association House, Tavistock Square, W.C.1, on Tuesday, March 8th, at 9 p.m. Mr. A. G. Timbrell Fisher, *M.C.*, will deliver a lecture on "Manipulative surgery."

METROPOLITAN COUNTIES BRANCH: SOUTH MIDDLESEX DIVISION.—A meeting of the South Middlesex Division will be held at St. John's Hospital, Twickenham, on Wednesday, March 9th, 8.15 p.m., General business. 8.30 p.m., Discussion: "Treatment of cancer by non-operative means," to be opened by Dr. J. B. Cook, medical superintendent, West Middlesex Hospital.

METROPOLITAN COUNTIES BRANCH: SOUTH-WEST ESSEX DIVISION.—A meeting of the South-West Essex Division will be held at Whipps Cross Hospital, Leytonstone, on Tuesday, March 1st, at 3.30 p.m., when Dr. J. C. Muir, medical superintendent of the hospital, will give a clinical demonstration.

MIDLAND BRANCH: CHESTERFIELD DIVISION.—A meeting of the Chesterfield Division will be held at the Maternity Hospital, Chesterfield, to-day (Friday, February 25th), at 8.15 p.m. Dr. Miles Phillips, professor [illegible] of Sheffield, will give an address on "[illegible]."

NORTH OF ENGLAND BRANCH: BISHOP AUCKLAND DIVISION.—A meeting of the Bishop Auckland Division will be held in the Cottage Hospital, Bishop Auckland, to-day (Friday, February 25th), at 8 p.m., when Dr. E. Farquhar Murray will give a lecture on "Some modern aspects of obstetrics and gynaecology."

NORTH OF ENGLAND BRANCH: NEWCASTLE-ON-TYNE DIVISION.—Mr. H. S. Elphick, M.R.C.V.S., will give a lecture on March 10th, at 8.30 p.m., in the Library of the Royal Victoria Infirmary, on "Pregnancy and parturition in veterinary practice." The Division is holding a reception and dance with cabaret about the end of March or beginning of April. The arrangements are in the hands of a subcommittee, and details will be announced shortly.

NORTH OF ENGLAND BRANCH: SUNDERLAND DIVISION.—A dance in aid of the British Medical Association Charities Fund will be held in Meng's Rooms, Sunderland, on Thursday, March 3rd. Reception by Dr. L. M. H. Ross, chairman of the Sunderland Division, and Mrs Ross. Reception, 8 p.m.; dancing, 8.30. Tickets 10s. 6d. Carriages, 1 a.m. Application for tickets should be made to Dr. MacMurray, North Grange, Stockton Road, Sunderland. A scientific meeting of the Division will be held at the Royal Infirmary, Sunderland, on Wednesday, March 16th, at 8.15 p.m. Mr. F. C. Pybus, M.S., F.R.C.S., will give an address on deformities. All members of the Division are invited to be present.

NORTHERN COUNTIES OF SCOTLAND BRANCH.—A clinical meeting of the Northern Counties of Scotland Branch will be held at the District Asylum, Inverness, on Friday, March 11th, at 3 p.m.

SURREY BRANCH: GUILDFORD DIVISION.—At the meeting of the Guildford Division to be held at the Royal Surrey County Hospital, Guildford, on Thursday, March 3rd, at 4 p.m., there will be a demonstration of cases. Tea served at 3.45 p.m.

SURREY BRANCH: REIGATE DIVISION.—A meeting of the Reigate Division will be held at the East Surrey Hospital, Reigate, on Tuesday, March 8th, at 8.45 p.m. Dr. Stanley Dodd will give an address on gynaecology.

SUSSEX BRANCH: HASTINGS DIVISION.—The next meeting of the Hastings Division will be held at the Queen's Hotel, Hastings, on Tuesday, March 1st, at 8.15 p.m. Dr. G. J. Langley, M.B.E., will give a lecture on "Auricular fibrillation: its nature and treatment," which will be illustrated by lantern slides. Coffee will be served at 8.15 p.m.

YORKSHIRE BRANCH: DEWSBURY DIVISION.—A meeting of the Dewsbury Division will be held, by invitation of the medical staff, at the Dewsbury Infirmary on Tuesday, March 1st.

YORKSHIRE BRANCH: HUDDERSFIELD DIVISION.—A British Medical Association Lecture will be given at the Huddersfield Royal Infirmary on Wednesday, March 9th, at 8 p.m., by Professor Miles Phillips of Sheffield on "Some obstetrical emergencies." Members of other Divisions are invited to attend, and light refreshments will be provided after the lecture.

YORKSHIRE BRANCH: WAKEFIELD, PONTEFRACT, AND CASTLEFORD DIVISION.—A meeting of the Wakefield, Pontefract, and Castleford Division will be held at the Bull Restaurant, Westgate, Wakefield, on Thursday, March 10th. Dr. G. W. Watson, physician to the Leeds General Infirmary, will lecture on the early signs of phthisis. Supper at 7.45 p.m. (2s. 6d.) will precede the lecture.

Meetings of Branches and Divisions.

ULSTER BRANCH.

THE winter meeting of the Ulster Branch was held in the Medical Institute, Belfast, on January 20th, with the President, Dr. JOHN MORROW, in the chair. On the proposal of the President, the congratulations of the Branch were tendered with acclamation to Sir Thomas Houston on the honour bestowed on him by the King.

Sir THOMAS HOUSTON gave a brief history of the enterococcus, from its detection in 1899 in cases of mucous membranous enteritis. It was proved to be identical with the *Streptococcus faecalis*, a normal denizen of the alimentary canal, and devoid of pathogenicity. It had been found to attain very variable degrees of virulence in certain inflammatory conditions; it occurred in epidemics, and frequently coincided with influenza. French pathologists had written much about it, and connected it with appendicular abscess, biliary cirrhosis, laryngitis, pleurisy, a form of septicaemia, and "rheumatism," in which it assumed the anaerobic form. The fermentation of sugars by this organism was next dealt with, and reference made to its resistance to heat, first described by Houston and McElroy, and confirmed independently in 1921. The conditions in France seemed to favour the non-mannite fermenting form of enterococcus. Sir Thomas Houston then briefly reviewed the evidence that this coccus was the cause of chronic ulcerative colitis. It appeared that this non-mannite fermenting enterococcus could be invariably isolated from cases of ulcerative colitis, and sometimes from cases that were not ulcerative colitis. The results of agglutinative tests, of inoculations into rabbits, and of vaccine therapy supported the theory. Details were given of many cases.

Dr. W. CALWELL gave a short account of a case of tabes dorsalis, where the Argyll Robertson pupil was the earliest symptom.

Professor ANDREW FULLERTON, P.R.C.S.I., described a case of removal of the colon for multiple papillomata, and showed the specimens. An unmarried woman, aged 28, of poor mental development, had complained for two to three years of irregularity of the bowels and passage of blood. The operation was described in detail; healing followed by first intention. A portion of one of the tumours proved on examination to be a papillomatous adenoma. He reported a case of diverticulum of the bladder in a man, aged 55 years, who had had long-standing frequency of micturition, with pus cells and bladder epithelium in the urine. Details were given of the cystoscopical examination, and the stages of the operation for the removal of the cyst were described. Complete recovery of the patient had followed, and a cystogram taken a month later showed a normal bladder. Professor Fullerton also read notes of a case of solitary cyst of the kidney in a married woman, aged 45. An unexpected swelling in the right lumbar region was found not long after her last child was born. Differential ureteral catheter specimens showed a difference of specific gravity. The right kidney was found to contain one large cyst and some small ones; it was removed. Details were given of the examination of the specimen, and of the operation, and the question of unilateral diuresis was discussed.

Dr. H. C. C. DEANE (Armagh) reported a case of ruptured uterus during labour in a young woman with unreduced shoulder presentation; a successful Caesarean section was performed five hours later. He also read notes of a successful case of Caesarean section in a woman, aged 44, who had been married fifteen years, and of whom this was the only pregnancy; he removed the uterus.

Professor LOWRY and Dr. DARLING (Lurgan) congratulated Dr. Deane on his results, and observed that if ante-natal care had been taken, and the patient had come to Dr. Deane during pregnancy, instead of five hours after rupture, the condition would have been rectified.

METROPOLITAN COUNTIES BRANCH: LEWISHAM DIVISION.

A MEETING of the Lewisham Division was held on January 18th at the Town Hall, Catford, when Mr. C. A. JOLL gave an address on "The diagnosis and treatment of diseases of the gall bladder and bile ducts." Mr. Joll said that the gall bladder might cause long-standing dyspepsia or gastritis, and that infection might reach it from the duodenum or through the portal system from the alimentary canal. Stones were of two types—the aseptic, composed of cholesterin, and the septic. The former were single, large, smooth or slightly nodular, light in colour, and crystalline. Septic stones were multiple, smaller, and composed of bilirubin with calcium carbonate. Symptoms of gall stones were not always colic and acute inflammation, but might be dyspepsia and flatulence after food, nausea, sudden vomiting, and chills in the evening. Stones of longer duration caused symptoms similar to duodenal ulcer, and if inflammation was present, anorexia, pyrexia, vomiting, and tenderness over the right abdomen resulted. Radiological examination was valuable if dyes were given by the mouth or intravenously; nearly 90 per cent. successful diagnoses could be so obtained. Barium meals were of less value, and test meals were unreliable, but the Einhorn tube was useful, and it could be shown that magnesium sulphate solution, yolk of egg, cream, or oleic acid produced a rush of bile. Medical treatment might be tried for three months; if it was not successful surgical measures were required. Urotropine in doses of 50 to 100 grains t.d.s. might be given by mouth. The formalin in the urine might cause frequency and pain, so large doses of alkali were given to neutralize the formalin. Considerable quantities of fluid, magnesium sulphate, yolk of egg, and cream were administered. Patients were kept in bed a few days before an operation, and glucose and saline were given before it, especially if jaundice was present and calcium chloride was injected intravenously. Blood transfusion was sometimes useful. Anaesthesia was a critical factor in successful operating; nerve blocking, and gas and oxygen were used. Cholecystectomy was safe and satisfactory; in 150 cases there had been no death.

Drs. THOMSON, PRATT, BEATTIE, CHARSLEY, and BUCHAN joined in the discussion. A vote of thanks was accorded to the lecturer.

SOUTHERN BRANCH: PORTSMOUTH DIVISION.

A MEETING of the Portsmouth Division was held at the Queen's Hotel, Southsea, on February 10th, with Dr. MEARNS FRASER in the chair. At the conclusion of supper, and after the ordinary business had been concluded, a very instructive address on poliomyelitis was given by Dr. JAMES COLLIER (London), who dealt with the epidemiological, clinical, and pathological aspects of the disease, and referred to the recent outbreaks at Uppingham and Broadstairs. The address was followed by an interesting discussion in which the following, among others, took part: Drs. BEATON, VALENTINE, MUNRO FORDE, KEY, ORD, DEWEY, JEANS, LYTLE, DOROTHEA TAYLOR, and FARNCOMBE. A very hearty vote of thanks, proposed by Dr. STEPHEN GREEN and seconded by Dr. MCCARTER, was accorded to Dr. Collier. The total attendance at the meeting numbered seventy-five, of whom thirty-one sat down to supper.

SUSSEX BRANCH: HASTINGS DIVISION.

Annual Dinner.

THE Hastings Division held its sixth annual dinner at the Royal Victoria Hotel, St. Leonards, on February 11th. One hundred members and guests sat down and enjoyed the excellent meal.

The chairman of the Division, Dr. E. C. MACKAY, presided, others present including the Bishop of Lewes, Dr. G. C. Anderson (Deputy Medical Secretary, British Medical Association), Mr. Britten-Austin, Councillor A. D. Thorpe, J.P., Professor C. Lloyd-Morgan, LL.D., F.R.S., Councillor A. Blackman, and Dr. T. Reed (honorary secretary, Hastings Division).

After the loyal toast had been drunk to musical honours, the CHAIRMAN proposed the toast of "The British Medical Association." After pointing out some of its earlier struggles and difficulties, he mentioned that its membership was now almost 90 per cent. of the total registered medical population of the Empire. At the present time it was the first body consulted when the Government wished to know what was the contribution of medical thought to the solution of great national problems. Dr. Mackay showed how the Association had been instrumental in moulding such reforms as the Factory Acts, Poor Law, prisons, and public health services. Dr. Mackay regretted the poor support which the profession gave to medical charities, and made an urgent appeal to the Division to remove this slur.

Dr. G. C. ANDERSON replied to the toast and referred especially to the attitude of the newspaper press towards the profession, and especially the Association. He also referred to the Dogs Protection Bill which was likely to be soon introduced to the House of Commons. The British Medical Association was considering the advisability of drawing up a counter-petition, to be signed by medical men against this bill, which would be to the detriment of the public.

Dr. CONWAY MORGAN proposed the toast of "The Allied Professions" in a witty speech, which was responded to by the BISHOP OF LEWES (honorary chaplain), Mr. A. D THORPE, and Mr. W. E. MEADS for the British Dental Association. Mr. Thorpe claimed that the law belonged to the healing profession, for nothing was so healing as a long course of expensive litigation! Dr. CHARNOCK SMITH proposed "The Guests," to which Mr. BRITTEN-AUSTIN responded. He observed that the chairman had been a little grieved that the public had referred to the British Medical Association as a trade union. He seemed unaware of the honour done the Association, when one considered that trade unions were mightier than the press, more vigorous in discipline than the Church, above the law. It was with a thrilling pride that he found himself the guest of the greatest trade union in the world.

It was the only trade union which primarily existed, not for the protection of its own members, but for the protection of the public. Professor LLOYD MORGAN also replied for the guests. Dr. HOWE proposed the toast of "The Chairman," to which Dr. MACKAY briefly responded. A humorous entertainment was provided by Leslie Weston.

YORKSHIRE BRANCH: WAKEFIELD, PONTEFRACT, AND CASTLEFORD DIVISION.

A MEETING of the Wakefield, Pontefract, and Castleford Division was held at the Great Bull Restaurant, Wakefield, on February 10th, when Dr. GIBSON was in the chair.

Dr. BARNES gave an interesting address on diet. In some general considerations he emphasized the fact that the general population get their energy from the wheaten loaf and that the most "strengthening" food after all was bread-and-butter and milk. The best proportion of protein in the dietary was not settled, but the position was still best described by Bayliss's aphorism, "Take care of the calories and the proteins will take care of themselves." In this country there was no need for a slogan "Eat more meat."

In discussing vitamins attention was drawn to the fact that scurvy could be overlooked, and after an extensive experience with scurvy the speaker was of opinion that probably a subscorbutic state was not at all uncommon. The cheapest sources of vitamins were fish, especially herrings, oranges, and salads, and perhaps marmite.

In referring to diet in disease, rickets and diabetes were excluded. In pyrexia the value of carbohydrates and the limitations of proteins were referred to. In diseases of the vascular system systematic undernutrition was advocated for heart diseases, whilst in arterio-sclerosis the patient rather than the disease should be treated. Attention was drawn to the fact that in overweight diabetics the blood pressure often fell when the weight and hyperglycaemia were reduced. In renal diseases the presence of haematuria indicated a glomerular lesion such as finally led to uraemia, and here carbohydrates should be pushed at the expense of the fats, and particularly carbohydrates. The presence of marked œdema, on the other hand, indicated limitation of fats, whilst proteins or even urea might be given.

Obesity was worthy of much attention now that its important relationship to high blood pressure and diabetes was realized. A very strict limitation of diet was urged. In alimentary diseases one of the chief points emphasized was the futility of dieting for "flatulent dyspepsia" as if it were due to fermentation; attention was drawn to the fact that practically no alimentary diseases were due to difficulty of digestion of an ordinary diet, and that great harm might be done by suggesting to a patient that his food caused the abdominal pain. In cases of peptic ulcer the diet during the remissions and after operation must be controlled. The general principle seemed to be that the diet must be devoid of appetizing properties. In enteritis treatment by carbohydrates, fluids, and restriction of proteins was advocated. In the dietetic treatment of constipation continual attention must be paid to the psychological issue, and the speaker ended by suggesting that the soapy residue from milk fats was, at body temperature, a better and more natural lubricant than liquid paraffin.

In the subsequent discussion Drs. GIBSON, STEVEN, THOMAS, RADCLIFFE, HILLMAN, and SCHOLEFIELD took part.

Naval and Military Appointments.

ROYAL NAVAL MEDICAL SERVICE.

Surgeon Commander W. R. Harrison, O.B.E., is placed on the retired t with the rank of Surgeon Captain.
The appointment of Surgeon Commander B. S. Robson to the *Iphurst* is cancelled.

ROYAL NAVAL VOLUNTEER RESERVE.

Probationary Surgeon Sublieutenants to be Surgeon Sublieutenants: G. Ungley and D. S. Buchanan.

ROYAL ARMY MEDICAL CORPS.

Lieut.-Colonel P. G. Easton, C.B.E., D.S.O., retires on retired pay.
Major J. J. H. Beckton, half-pay list, late R.A.M.C., retires on retired y.
The following Captains to be Majors: D. S. Martin, with precedence xt below B. H. C. Lea-Wilson; W. L. E. Reynolds, M.C. (prov.), W. K. mpbell, D.S.O., M.B.E., M.C. (prov.), C. G. G. Keane, O.B.E.
Temporary Captain S. E. Ilphick relinquishes his commission on count of ill health and retains the rank of Captain.
Lieutenant (on probation) R. V. Franklin, from the seconded list, is stored to the establishment.
The following Lieutenants (on probation) are confirmed in their rank: P. M. Anderson, J. D. Borham, P. F. Palmer, D. Bluett, C. E. Eccles, M. Collins, and J. A. Chapel.

MILITIA.

ROYAL ARMY MEDICAL CORPS.

Majors T. Hampson, M.C., and F. Jefferson relinquish their commissions d retain the rank of Major.

TERRITORIAL ARMY.

ROYAL ARMY MEDICAL CORPS.

Captain S. J. C. Holden to be Major.
Captain A. H. Fullerton to be Major (prov.).
Captain A. J. Bado, R.A.M.C., to be Divisional Adjutant 43rd (Wessex) ivision, vice Captain A. Rodd to half-pay.
To be Captains (prov.): Lieutenants W. Simpson, R. N. Craig, and . S. Creed.

COLONIAL MEDICAL SERVICES.

Dr. L. H. Booth promoted Senior Medical Officer, Nigeria. Dr. J. C. ranklin, Medical Officer, Nigeria, has been invalided from the Service.

VACANCIES.

BARRY URBAN DISTRICT COUNCIL.—Surgeon to the Accident and Surgical Hospital. Salary at the rate of £750 per annum, rising to £900.

BRISTOL ROYAL INFIRMARY.—(1) Two House-Physicians. (2) Four House-Surgeons. (3) House-Surgeon to the Ear, Nose, and Throat Department. (4) House-Surgeon to the Gynaecological, Ophthalmic, and Dermatological Departments. (5) Obstetric House-Physician. (6) Casualty House-Surgeon. (7) Dental House-Surgeon. Salary for (1) to (6) £80 per annum, or £100 if candidate has previously held resident appointment in the Infirmary, and for (7) £80 per annum if resident, or £116 per annum non-resident.

BROMLEY BOROUGH.—Assistant Medical Officer of Health. Salary £600 per annum.

CHESTERFIELD AND NORTH DERBYSHIRE ROYAL HOSPITAL.—Fifth House-Surgeon. Salary at the rate of £160 per annum.

EAST RIDING MENTAL HOSPITAL, Beverley.—Medical Superintendent. Salary £900 per annum, increasing to £1,000.

EAST SUFFOLK ADMINISTRATIVE COUNTY.—Assistant County Medical Officer of Health and Medical Officer of Health for Rural District of Hoxne. Salary £625 per annum.

FEDERATED MALAY STATES: CENTRAL MENTAL HOSPITAL.—Second Assistant Medical Superintendent. Salary £700—£35—£1,120 per annum, with temporary allowance of 10 and 20 per cent. to unmarried and married officers respectively.

GREAT YARMOUTH COUNTY BOROUGH.—Assistant Medical Officer of Health and Assistant Tuberculosis Officer. Salary £600 per annum.

HOLLAND (LINCS) COUNTY COUNCIL.—Assistant Medical Officer of Health (male). Salary £600 per annum.

HULL EDUCATION COMMITTEE.—Assistant School Medical Officer. Salary £600 per annum.

LEICESTER ROYAL INFIRMARY.—(1) House-Physician. (2) House-Surgeons. Salary at the rate of £120 and £125 per annum respectively.

LEICESTERSHIRE COUNTY COUNCIL.—Assistant County Medical Officer (male). Salary £750 per annum.

LONDON FEMALE LOCK HOSPITAL, 283, Harrow Road, W.—Surgical Registrar. Honorarium £100 per annum.

LONDON JEWISH HOSPITAL, Stepney Green, E.1.—(1) Medical Registrar and Out-patient Assistant. (2) Surgical Registrar. Honorarium at the rate of £50 per annum each.

LONDON LOCK HOSPITAL, 91, Dean Street, W.—Surgical Registrar. Honorarium £100 per annum.

MANCHESTER: ANCOATS HOSPITAL.—Honorary Physician.

MANCHESTER CITY.—Assistant Medical Officer to Public Health Department (Baguley Sanatorium), unmarried. Salary £350 per annum.

MANCHESTER: ROYAL MANCHESTER CHILDREN'S HOSPITAL.—(1) Resident Surgical Officer at Pendlebury; salary at the rate of £80 per annum, and eligible after six months for reappointment as Resident Medical Officer, salary at the rate of £120. (2) Assistant Medical Officer (Out-patients' Department), non-resident; salary at the rate of £150 per annum, and eligible after six months for appointment as Medical Officer, salary at the rate of £200 per annum.

NATIONAL HOSPITAL, Queen Square, W.C.1.—Resident Medical Officer. Salary £200 per annum

NOTTINGHAM: CITY MENTAL HOSPITAL.—Junior Assistant Medical Officer (male). Salary £350 per annum, rising to £400, with additional £50 for D.P.M., and £10 for M.P.C. per annum.

NOTTINGHAM: GENERAL HOSPITAL.—House-Physician. Salary at the rate of £150 a year.

OXFORD: RADCLIFFE INFIRMARY AND COUNTY HOSPITAL.—(1) House-Physician. (2) Casualty House-Surgeon. Salary at the rate of £120 per annum each.

PLAISTOW: ST. MARY'S HOSPITAL FOR WOMEN.—Honorary Assistant Surgeon.

ROYAL FREE HOSPITAL, Gray's Inn Road, W.C.1.—House-Physician to the Children's Department (woman).

ROYAL NATIONAL ORTHOPAEDIC HOSPITAL, 234, Great Portland Street, W.1.—House-Surgeon. Salary £150 per annum.

ST. MARY ISLINGTON INFIRMARY, Highgate Hill, N.19.—Assistant Medical Officer (male). Salary £350 per annum.

ST. MARYLEBONE HOSPITAL, Ladbroke Grove, W.10.—Third Assistant Medical Officer (male). Salary £300 per annum.

ST. THOMAS'S HOSPITAL, S.E.—(1) Resident Assistant Physician. (2) Medical Registrar.

SEAMEN'S HOSPITAL SOCIETY: HOSPITAL FOR TROPICAL DISEASES, Endsleigh Gardens, W.C.1.—Medical Superintendent. Salary £250 per annum.

SHEFFIELD UNIVERSITY.—Senior Laboratory Assistant for the Bacteriological Laboratories. Wages £5.

SOUTHAMPTON: ROYAL SOUTH HANTS AND SOUTHAMPTON HOSPITAL.—Junior House-Surgeon (male, unmarried). Salary at the rate of £150 per annum.

SOUTHEND-ON-SEA COUNTY BOROUGH.—Assistant Medical Officer of Health and Assistant School Medical Officer (male). Salary £600 per annum, rising to £700.

STOKE-ON-TRENT CITY AND COUNTY BOROUGH.—Medical Officer of Health. Salary £1,400 per annum.

WEST BROMWICH COUNTY BOROUGH.—Assistant Medical Officer of Health. Salary £600 per annum.

WEST LONDON HOSPITAL, Hammersmith Road, W.6.—(1) Honorary Medical Registrar; honorarium £100. (2) House-Physician. (3) Two House-Surgeons. Salary at the rate of £100 per annum for (2) and (3).

WESTERN OPHTHALMIC HOSPITAL, Marylebone Road, N.W.1.—Senior and Junior Non-Resident House-Surgeons. Salary £150 and £100 per annum respectively.

WHITEHAVEN AND WEST CUMBERLAND HOSPITAL.—Junior House-Surgeon (male). Salary £100 per annum.

WILLESDEN MUNICIPAL HOSPITAL.—Resident Medical Officer. Salary £150 per annum.

WOLVERHAMPTON COUNTY BOROUGH.—Assistant Medical Officer for Maternity and Child Welfare Work. Salary £600 per annum.

WORTHING HOSPITAL.—House-Surgeon. Salary at the rate of £150 per annum.

CERTIFYING FACTORY SURGEONS.—The following vacant appointments are announced: Audley (Staffs), Calvert (Bucks). Applications to the Chief Inspector of Factories, Home Office, Whitehall, S.W.1.

This list of vacancies is compiled from our advertisement columns, where full particulars will be found. To ensure notice in this column advertisements must be received not later than the first post on Tuesday morning.

APPOINTMENTS.

RIGGALL, Robert M., L.R.C.P.Lond., M.R.C.S.Eng., L.R.C.S.Ed., a Member of the Honorary Clinical Psychological Staff of the West End Hospital for Nervous Diseases.

THOMSON, M. Sydney, M.A., M.D., M.R.C.P., Junior Physician to the Skin Department at King's College Hospital.

WILSON, D. E., M.B., Ch.B.Aberd., Certifying Factory Surgeon for the Rhynie District, co. Aberdeen.

ROYAL EAST SUSSEX HOSPITAL, Hastings.—*Surgeon:* H. S. Gabb, M.B., B.Ch.Cantab. *Assistant Surgeon:* G. H. Caiger, M.B.Cantab, F.R.C.S.

DIARY OF SOCIETIES AND LECTURES.

ROYAL SOCIETY OF MEDICINE.

Section of Odontology.—Mon., 8 p.m., Dr. H. W. Barber: Relationship of Diseases of the Skin to Dental Infection; Mr. E. C. Sprawson: [illegible] be shown.

[illegible] 8.30 p.m., Discussion: Treatment of Pes [illegible] Rocyn Jones, followed by Mr. Naughton Dunn and others.

Section of Pathology.—Tues., 8.30 p.m., Laboratory Meeting at the Lister Institute, Chelsea Gardens, S.W.1. Papers—M. Robertson: Werbitzki Phenomenon in a Free-living Flagellate; P. Bruce White: Reactions of Alcohol-solu[illegible]lt and Serum; M. C. Maitland: [illegible]s from Virulent Types of *B. diphthiæ* [illegible] " and "Smoothness" in Relation to [illegible] Schütze: "Augmentor" Effects in Growth of *B. pestis*; H. B. Maitland: Antigenic Properties of Foot-and-Mouth Virus in Relation to Prophylaxis; T. Lumsden: *In vitro* Experiments on Immunity to Cancer.

Section of Tropical Diseases and Parasitology.—Wed., 5.30 p.m., Dr. P. Manson-Bahr: Plasmochin in Malaria; Dr. Dyce Sharp: Onchocerciasis; Professor R. T. Leiper: Geographical Distribution of *Physaloptera caucasica* v. Linstow in Africa.

Section of Surgery.—Wed., 8.30 p.m., Discussion: Surgical Treatment of Chronic Non-tuberculous Arthritis; to be opened by Mr. C. Max Page, followed by Dr. Beddard and Mr. R. C. Elmslie.

Section of Balneology and Climatology.—Thurs., 4.30 p.m., Discussion: The Breakdowns of Middle Life; to be opened by Dr. Campbell McClure, Dr. Wybauw (Spa), and Dr. Fortescue Fox.

Section of Laryngology.—Fri., 4 p.m., Cases. 5 p.m., Dr. Irwin Moore: Pathology of Oesophagectasia (dilatation of oesophagus without anatomic stenosis at the cardiac orifice). Cases and Specimens.

Sections of Anaesthetics and Odontology.—Fri., 8.30 p.m., Special Joint Discussion on Anaesthetics in Dental Operations. Openers: Dr. Bellamy Gardner (Anaesthetics) and Mr. Ivan Spain (Odontology).

Section of Otology.—Sat., 9.30 a.m., Cases.

ROYAL COLLEGE OF PHYSICIANS OF LONDON, Pall Mall East, S.W.1.—Tues. and Thurs., 5 p.m., Milroy Lectures by Dr. W. F. Dearden: Health Hazards in the Cotton Industry.

ROYAL COLLEGE OF SURGEONS OF ENGLAND, Lincoln's Inn Fields, W.C.—Mon., 5 p.m., Professor V. Zachary Cope: Shock and Collapse, with Special Reference to Acute Abdominal Disease. Wed. and Fri., 5 p.m., Sir Arthur Keith: Recent Researches carried out in the Museum.

HUNTERIAN SOCIETY, Cutlers' Hall, Warwick Lane, E.C.—Mon., 9 p.m., Hunterian Oration by Mr. W. Girling Ball: The Value of Modern Methods of Investigation in the Diagnosis and Treatment of Haematuria.

POST-GRADUATE COURSES AND LECTURES.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION.—Special Lecture at the Medical Society, 11, Chandos Street, W.1., Thurs., 5 p.m., The Differential Diagnosis of Some Acute Rashes. Open to all members of the medical profession, without fee. *London Lock Hospital*, Dean Street, W.1: Special Course in Venereal Diseases. Clinical work daily and special lectures. *National Hospital*, Queen Square, W.C.1: Special Course in Neurology. Instruction daily in the Out-patient Department and special lectures and demonstrations. All information as to fees, etc., obtainable from the Fellowship of Medicine, 1, Wimpole Street, W.1.

CENTRAL LONDON THROAT, NOSE AND EAR HOSPITAL, Gray's Inn Road, W.C.1.—Fri., 4 p.m.

HOSPITAL FOR SICK CHILDREN, Great Ormond Street, W.C.1.—Thurs., 4 p.m., Ringworm.

LONDON SCHOOL OF DERMATOLOGY, St. John's Hospital, Leicester Square, W.C.2.—Tues. and Thurs., 5 p.m., Cutaneous Syphilis.

NATIONAL HOSPITAL, Queen Square, W.C.1.—Mon., Tues., Thurs., and Fri., 2 p.m., Out-patient Clinics. Mon., 12 noon, Pathology of the Nervous System; 3.30 p.m., Borderland of Epilepsy. Tues., 3.30 p.m., Mental Dissociation and Double Personality. Thurs., 3.30 p.m., Vertigo. Fri., 12 noon, Anatomy and Physiology of the Nervous System; 3.30 p.m., Migraine. Operations: Tues. and Fri., 9 a.m.

NORTH-EAST LONDON POST-GRADUATE COLLEGE, Prince of Wales's General [illegible] Mon., 10 a.m., Surgical Clinic; 2.30 p.m., [illegible] lical Cases; 2.30 to 5 p.m., Medical, Surgical, Operations. Tues., 2.30 p.m., Special Demon- 2.30 to 5 p.m., Medical, Surgical, Throat, ations. Wed., 2.30 to 5 p.m., Medical Skin Thurs., 11.30 a.m., Dental Clinics; 2.30 to d Ear, Nose, and Throat Clinics; Operations. , and Ear Clinics; 2.30 to 5 p.m., Surgical, ases Clinics; Operations.

POST-GRADUATE HOSTEL, Imperial Hotel, Russell Square, W.C.1.—Mon., 9 p.m., Ladies' Night: The History of Bloomsbury.

ROYAL NORTHERN HOSPITAL, Holloway Road, N.—Tues., 3.15 p.m., Safety in Anaesthesia.

WEST LONDON HOSPITAL POST-GRADUATE COLLEGE, Hammersmith, W.6.—Mon., 10 a.m. to 1 p.m., [illegible]artment, Surgical Wards; 2 p.m., S[illegible]ye Departments. Tues., 10 a.m. to 1 [illegible] Demonstrations in Venereal Diseases [illegible] Wards, Throat, Nose, and Ear D[illegible]m. to 1 p.m., Children's Medical [illegible] [illegible]ration in Medical Pathology; [illegible] [illegible]nt. Thurs., 10 a.m. to 1 p.m., N[illegible] [illegible] of Fractures; 2 p.m., Eye and [illegible] [illegible]gical Ward. Fri., 10 a.m. to 1 p.m., Gynaecological Operations, Dental, Skin, and Electrical Departments; 2 p.m., Throat, Nose, and Ear Department. Sat., 10 a.m. to 1 p.m., Bacterial Therapy Department, Children's Medical Department. Daily: Operations, Medical and Surgical Out-patients at 2 p.m.

GLASGOW POST-GRADUATE MEDICAL ASSOCIATION.—At the Lock Hospital: Wed., 4.15 p.m., Female Venereal Diseases.

JAMES MACKENZIE INSTITUTE FOR CLINICAL RESEARCH, St. Andrews.—Tues., 4 p.m., Unresolved Pneumonia.

MANCHESTER ROYAL INFIRMARY.—Tues., 4.15 p.m., Graves's Disease from the Surgical Standpoint. Fri., 4.15 p.m., Demonstration of Surgical Cases.

MANCHESTER: St. Mary's Hospitals (Whitworth Street West Branch).—Fri., 4.30 p.m., A Visit to the Wards.

SHEFFIELD UNIVERSITY POST-GRADUATE CLINICS.—At Royal Hospital: Fri., 3.30 p.m., Neurological Cases.

Coventry Division: Dr. A. T. W. Forrester on Early Ment Cases.
Dewsbury Division: Dewsbury Infirmary.
Hastings Division: Queen's Hotel, Hastings. Dr. G. J. Langle on Auricular Fibrillation, 8.15 p.m.
South-West Essex Division: Whipps Cross Hospital, Leyto stone. Clinical Demonstration by Dr. J. C. Muir, 3.30 p.m.
2 Wed. London: Medical Officers of Public Schools Subcommittee 2.30 p.m.
3 Thurs. London: Disciplinary Subcommittee of Insurance Acts Com mittee, 2.30 p.m.
Bournemouth Division: Annual Dinner, Royal Bath Hote 7.30 p.m.
Guildford Division: Royal Surrey County Hospital, 4 p.m.
Nuneaton and Tamworth Division: Tamworth General Hospita Mr. A. B. Danby on Prevention in Obstetrics, 3.30 p.m.
Sunderland Division: Dance, Meng's Rooms, Sunderland, 8 p.m
4 Fri. London: Conference *re* Spa Treatment for Insured Persons 10 a.m.
London: Science Committee, 2.30 p.m.
8 Tues. Reigate Division: East Surrey Hospital, Reigate. Dr. Stanle Dodd on Gynaecology, 8.45 p.m.
St. Pancras Division: B.M.A. House, Tavistock Square, W.C.1 Mr. A. G. Timbrell Fisher on Manipulative Surgery, 9 p.m.
South Essex Division: Palace Hotel, Southend. Dr. C. Gran Pugh will give an address, 8.30 p.m.
9 Wed. London: Hospitals Committee, 2.15 p.m.
Dumbartonshire Division: Dinner, North British Statio Hotel, Queen Street, Glasgow, 7.30 p.m.
Huddersfield Division: Huddersfield Royal Infirmary. B.M.A Lecture by Professor Miles Phillips on Some Obstetrica [illegible]
[illegible] John's Hospital, Twickenham.
[illegible] operative Treatment of Cancer.
10 Thurs. [illegible] Royal Victoria Infirmary. Mr. and Parturition in Veterinary [illegible]
[illegible] d Division: Bull Restaurant, [illegible]n Early Signs of Phthisis, [illegible] lecture.
[illegible] [illegible]l, Swansea, 8.15 p.m.
11 Fri. [illegible] 2.30 p.m.
[illegible] Branch: District Asylum, Inverness, 3 p.m.
15 Tues. [illegible] p.m.
16 Wed. [illegible] Sunderland. Mr. F. C. [illegible]
18 Fri. [illegible]ance, B.M.A. House, [illegible]
24 Thurs. [illegible] [illegible] ral Hospital, Swansea, 8.15 p.m.

BIRTHS, MARRIAGES, AND DEATHS.

The charge for inserting announcement of Births, Marriages, and Deaths is 9s., which sum should be forwarded with the notice not later than the first post on Tuesday morning, in order to ensure insertion in the current issue.

BIRTHS.

BARCLAY.—On February 20th, at 2, Greenhead Road, Huddersfield, the wife of William Barclay, M.B., F.R.C.S.Ed., a son.

BORHAM.—On February 14th, 1927, at 27, Marsham Street, Westminster, S.W., to Esmé, wife of John Douglas Borham, M.R.C.S., L.R.C.P., of the Royal Army Medical Corps, a son.

CUFF.—On January 30th, 1927, at Nicosia, Cyprus, to Anna, wife of Cyril H. Cuff, M.B., B.S., F.R.C.S.E., a son.

DEATHS.

GARBUTT.—On February 21st, Meggie Watson, the beloved wife of William J. Garbutt, M.B., C.M., 1, Bournbrook Road, Selly Park, Birmingham.

PHILLIPS.—On February 18th, 1927, at Hardwick Lodge, Streetly, George Arthur Phillips, J.P., M.R.C.S., in his 78th year.

Printed and published by the British Medical Association, at their Office, Tavistock Square, in the Parish of St. Pancras, in the County of London.

EPITOME OF CURRENT MEDICAL LITERATURE.

Medicine.

247. Epidemic Meningitis.

J. B. NEAL, H. W. JACKSON, and E. APPELBAUM (*Journ. Amer. Med. Assoc.*, December 11th, 1926, p. 1992), whose paper is based on a study of 654 cases, state that epidemic meningitis is a disease to which most persons have a natural immunity, as is shown by the fact that there were only fourteen instances of a second case in the same family, although most of the patients lived in crowded districts. As regards the seasonal incidence, 34.6 per cent. of the cases occurred in the first quarter of the year, 33.5 per cent. in the second quarter, 13.9 per cent. in the third, and 18 per cent. in the fourth. Of the total cases, 57.5 per cent. were males and 42.5 per cent. females. More cases occurred in the first year of life (166) than in any other year. The mortality for 627 cases was nearly 30 per cent. This high figure was due to: (1) the large percentage of children under 1 year of age; (2) the late stage of the disease when treatment was started; and (3) the high incidence of pneumonia or some complication not directly connected with the meningitis. Of 337 patients who were followed up, 276 (81.9 per cent.) made a complete recovery, while 61 (18.1 per cent.) showed sequelae. The most important and frequent sequela was deafness, which was usually bilateral, complete, and permanent. Visual defects occurred in 7 cases—in the form of irido-choroiditis in 6, leading to panophthalmitis in 5, and bilateral defective vision following hydrocephalus in one. In only 8 instances was there any indication of residual disturbances in mentality or intelligence, but 11 patients showed some form of paralysis of the cranial nerves or limbs, 2 developed sphincteric disturbances, and one complete transverse myelitis.

248. Focal Infection and Diabetes Mellitus.

D. COHEN and A. E. COHEN (*Urol. and Cutan. Rev.*, November, 1926, p. 650) remark that it is commonly observed in diabetes mellitus that *carbohydrate tolerance is greatly diminished* by acute infectious processes and that the patient's general condition often improves after the removal of some chronic focal infection. It is uncertain whether the removal of such foci exerts its beneficial influence through a general systemic effect or through an actual curative influence upon the disease itself. The nature of the injurious influence upon the pancreas is not known. Much emphasis has been laid upon obesity as an etiological factor. Various other factors have been incriminated, such as diet, heredity, nervous strain, arterio-sclerosis, syphilis, gout, gall-bladder disease, pregnancy, thyroid cysts, fibroid uteri, brain tumours, and infection. Foci of infection in the teeth, tousils, and gastro-intestinal tract are regarded as causes of diabetes through toxic absorption or entry of living organisms into the circulation. The authors report a case of diabetes in a man aged 60 who showed marked improvement in carbohydrate tolerance after removal of an enlarged infected prostate.

249. Tularaemia.

B. C. FARRAND (*Amer. Journ. Med. Sci.*, December, 1926, p. 853), who reports eleven illustrative cases, defines tularaemia as an acute infectious disease caused by the *Bacterium tularense*. It is divided into two types—the glandular and the typhoid. It is transmitted by blood-sucking insects that bite man and animals, and is characterized by marked prostration. The incubation period is from two to five days. It was first described by McCoy in 1911 as a "plague-like disease of rodents," and by Pearse in the same year as "deer-fly fever." It has also been called "rabbit fever" and "glandular type of tick fever." The name "tularaemia" was suggested by Edward Francis in 1921, since the disease was caused by the organism isolated by McCoy and Chapman in 1911 from squirrels in Tulare, County California. The disease has now been reported from twenty-three of the United States and in the district of Columbia. Transmission usually takes place by the wood-tick, which also transmits Rocky Mountain spotted fever. Infection may also be caused by briers and burs which have been in contact with infected material. Laboratory workers have been infected by the urine and faeces of rabbits. The glandular type is characterized by fever and prostration and the small reddened area at the point of infection, with inflammation and often suppuration of the corresponding lymphatic glands. In the typhoid type fever of varying degree lasts a considerable time. Treatment is symptomatic.

250. Conjugal Herpes Zoster.

H. BERNADOU (*Gaz. hebd. des Sci. Med. de Bordeaux*, December 5th, 1926, p. 774) states that the infectious nature of herpes zoster was first recognized in 1883 by Landouzy, who had observed some small epidemics of it, and later by Erb. Idiopathic zoster may be recorded as a specific infectious disease allied to the eruptive fevers. The causal organism is unknown. It is probably a filterable virus with a predilection for the spinal ganglia, and especially those most closely related to the visceral sympathetic—namely, the third and fourth cervical, the last nine dorsal, and the first two lumbar nerves. The disease has numerous resemblances to herpes febrilis, but whereas the vesical fluid in herpes febrilis is inoculable, especially on to the eye of a rabbit, the contents of the vesicles of herpes zoster always remain sterile. Bernadou reports the case of a woman, aged 35, who, after pain in the left side of the thorax for a week, developed herpes zoster in the tenth and eleventh left intercostal spaces. Three weeks later her husband, aged 40, had severe pain in the left scapular region, which gradually spread to the upper part of the thorax and was accompanied by fever and insomnia. Sixteen days after the onset two patches of herpes zoster appeared in the fourth and fifth left intercostal spaces. Neither the husband nor wife had any history or evidence of syphilis, or any other taint, nervous or otherwise, nor had they been exposed to any other case of herpes zoster, herpes febrilis, or varicella.

251. Infantile Myxoedema in Norway.

T. SKAAR (*Norsk Mag. f. Laegevid.*, October, 1926, p. 863) reviews the literature and records thirty-five personal cases of infantile myxoedema in Norwegian children. None of the cases were found north of Levanger, a town slightly to the north of Drontheim. In those districts where goitre was endemic only sporadic cases of myxoedema were found, so that Skaar concludes that the two diseases bear no relation to each other as regards their distribution in Norway. With the exception of one which developed after measles, all the cases were congenital. As regards the etiology of the disease, in no instance was there any question of blood relationship in the parents. On the other hand, in four cases, or in 11.4 per cent., the mother had goitre, and in one case the maternal grandmother also. Skaar points out that the value of this series of cases is that most of the patients had been kept under observation for several years so that their mental and somatic development could be estimated. It was found that even when treatment was commenced late—that is, between 10 and 15 years of age—*rapid improvement occurred*. The prognosis, therefore, is good even when treatment is delayed, but is better still when treatment is started early. It appears, however, that the patients rarely attain a height exceeding 150 cm., even under early treatment.

Surgery.

252. Liver Abscesses complicating Appendicitis.

I. V. REÖK (*Zentralbl. f. Chir.*, January 22nd, 1927, p. 196) states that the transient form of toxic jaundice which sometimes precedes an acute attack of appendicitis in young persons has a good prognosis, and almost invariably disappears after removal of the appendix. Liver abscesses, on the other hand, though of rare occurrence, have a high mortality; they are generally multiple, and may occur at the beginning or during the course of an acute or chronic attack, with or without operation, immediately after appendicectomy or after an interval. Emboli from the thrombosed vessels of the inflamed appendix are carried by the ileo-colic, mesenteric, and portal veins to the liver, where the bacteria, emboli, and toxins may produce an almost symptomless functional hepatic disturbance or multiple liver abscesses, according to the virulence of the organisms and the defensive powers of the body. The symptoms of liver involvement, which may entirely mask those of appendicitis, are tenderness in the upper abdomen, pain radiating to the shoulder, enlargement of the liver, and jaundice frequently simulating acute cholecystitis. The appendix should therefore be watched whenever these symptoms occur, especially in young persons. Treatment is only possible when a single accessible abscess, formed by the confluence of several, is present. Prophylaxis is therefore of great importance; this includes early removal of the diseased appendix, and tying off the ileo-colic vein as closely as possible to its junction.

with the mesenteric and resecting it (a procedure advocated by Braun as presenting no great technical difficulties) in all cases in which there is evidence of septic thrombi being carried to the liver, since any involvement of the liver which arises from appendicitis always passes along the direct blood stream.

253. Pyloro-duodenitis.

L. BOUCHUT and P. P. RAVAULT (*Lyon Méd.*, December 26th, 1926, p. 742) maintain that late gastric pains should not always be diagnosed as due to ulcer of the stomach, an opinion which is borne out by the numerous negative findings in operations for gastric ulcer. The symptomatic syndrome of pyloro-duodenitis shows all the classical characteristics of ulcerous dyspepsia—*such as pain after food, which is relieved* by the ingestion of hot water or an alkali, occasionally vomiting, and sometimes pyrosis with regurgitation of a hot acid fluid. The hydrochloric and total acidity are markedly increased. These attacks develop slowly and there are periods of remission. Besides gastric ulcer, conditions to be distinguished are appendicitis and vesiculitis. When these can be excluded the authors claim that the primary cause of the symptoms is a pyloro-duodenitis. They cite two cases with typical histories of chronic gastric and duodenal ulcers, in which operations were performed, and in neither was an ulcer found. The mucous membrane of the pylorus and duodenum appeared red and slightly granular with small superficial ulcerations, and microscopically showed an intense parenchymatous and interstitial inflammation. The treatment of this condition is that of chronic ulcer, but surgical intervention, such as gastro-entero-anastomosis, is not advised. According to the authors, cases of this type are remarkably amenable to the medical and dietetic treatment of ulcer.

254. Treatment of Epulis.

L. KUMER and H. WOLF (*Wien. klin. Woch.*, January 13th, 1927, p. 57) state that an epulis is to-day regarded by most authorities not as a true blastoma but as a chronic granuloma. Two types of it are distinguished—the so-called giant-cell epulis and the fibrous epulis. The treatment of both these forms has hitherto consisted in radical removal of the growth, together with the surrounding tissue, owing to great tendency to recurrence, which is equally pronounced in both forms. The disadvantages of a radical purely operative procedure are the more or less extensive resection of healthy neighbouring bones, the removal of teeth, the opening of the antrum of Highmore, the exposure of the mandibular canal, and, in extreme cases, partial resection of the upper or lower jaw. To obviate these great disadvantages systematic radium treatment of epulis has been tried at the First Surgical Clinic of the University and the radium department of the General Hospital at Vienna during the last four years, with the result that 8 out of 10 patients with epulis treated exclusively with radium were permanently cured. One of these patients was a girl suffering from multiple epulis fibrosa, who would have had to sacrifice all her teeth if the radical operation had been performed. In spite of these successes it was found that the epulis tissue was not particularly sensitive to radium, and in some cases the growths could not be destroyed entirely, even with very large doses of radium. In such cases the growth was excised and radium treatment applied to the area from which it had been removed. The authors add that although it is perhaps too early to speak of a permanent cure, 34 cases so treated present normal appearances now, and in 11 of the cases the treatment had been applied from two to four years previously. Only one patient showed a recurrence, which rapidly yielded to a fresh application of radium.

255. Local Immunity in Surgery.

PICARD (*Zentralbl. f. Chir.*, January 1st, 1927, p. 28) at a meeting of the Berlin Surgical Society alluded to the investigations by Wassermann and Besredka of local and general immunization, and described his clinical observations and experiments carried out in collaboration with Professor Citron. Filtrates of old cultures of streptococci or staphylococci were used, 150 cases in all being treated. In recent inflammatory processes the focus was opened and filled with a plug soaked in the vaccine. The cases treated included boils, carbuncles, abscesses of sweat glands, staphylomycoses in infants, whitlows, mammary abscesses, cellulitis, and acute osteomyelitis. In 80 per cent. satisfactory results were obtained, and only chronic processes, such as osteomyelitis and fistulae of the bones and soft parts, proved refractory to treatment. The best results were obtained in erysipelas. Five out of twelve cases were treated merely by application of strips of gauze soaked in the vaccine, while in the other seven the skin was scarified before the dressing was applied. In all the cases the temperature became normal in forty-eight hours. Experiments on animals confirmed the results of clinical observation. Picard therefore maintained that local immunization was in many cases preferable to chemical antiseptics, as it acted simultaneously on the cells and the bacteria, but so far from doing any harm to the cells, as was done by antiseptics, it increased their resistance. In the subsequent discussion Wolfsohn, Bier, and Martens expressed doubts as to how far the treatment was responsible for the good results obtained, especially in the case of erysipelas, in which recovery often took place within three days, even without treatment.

Therapeutics.

256. Xanthine Diuretics in Heart Failure.

H. M. MARVIN (*Journ. Amer. Med. Assoc.*, December 18th, 1926, p. 2043) has employed xanthine derivatives in the treatment of 77 adult patients with advanced congestive heart failure and much oedema. Many had ascites or hydrothorax, or both, in addition to anasarca. Moribund patients and those suffering from nephritis were excluded. Of the 77 patients 27 had rheumatic heart disease and 50 had arterio-sclerotic or hypertensive heart disease. In 36 cases digitalis alone caused oedema to disappear. Of the remaining 41, 13 patients were entirely relieved of oedema by one or more of these diuretics, 5 had good diuresis with great reduction of oedema, and 5 more were benefited moderately. Theobromine sodium salicylate, in doses of from 2.6 to 5.3 grams daily for five or six days, relieved only 2 patients out of a group of 8, although the remainder of this group responded well to theobromine or theophylline. Theobromine in doses of 0.6 gram thrice daily for two days was partially or entirely satisfactory in 7 out of 17 patients. Of the remaining 10 patients, 5 obtained excellent diuresis from theophylline. Theophylline was much the most powerful of the three diuretics, and relieved a number of patients who had failed to respond to the other two drugs. Its usefulness is limited somewhat by the nausea and vomiting it produces. Marvin considers it certain that a considerable proportion of cardiac patients can be relieved by these drugs after digitalis in full doses has failed. There is evidence that the xanthine diuretics are more effective in the arterio-sclerotic hypertensive heart disease group than in the rheumatic heart disease group.

257. A Contraindication to the Administration of Digitalis.

L. GALLAVARDIN (*Presse Méd.*, December 29th, 1926, p. 1637) refers to the uncertainty about the action of digitalis in diseases of the heart, sudden death having followed its ill-timed administration. These fatalities do not depend solely on the size of the dose or its method of administration, but are related to the condition of the heart. While even very large doses do not affect the healthy heart, the smallest dose will sometimes cause grave trouble in cardiac disease. Gallavardin states that sudden death after digitalis administration is caused by ventricular fibrillation. Auricular fibrillation is common and is well borne, but ventricular fibrillation inevitably leads to cardiac syncope or sudden death, and the author believes that a rhythmic syndrome, termed by him the "syndrome of alarm," exists which can be considered an expression of a prefibrillatory state of the ventricle. This syndrome, which can be easily detected by careful examination, is aggravated by even very small doses of digitalis. It consists of three marked symptoms—double rhythm, extra-systolic salvos, and attacks of tachycardia. The presence of these signs, Gallavardin maintains, should make physicians extremely prudent in the use of digitalis.

258. Tuberculin Treatment of Asthma.

C. R. ÖSTERGAARD (*Ugeskrift for Laeger*, January 13th, 1927, p. 24) supplements an earlier paper, in which he recorded observations on the treatment of eleven cases of asthma with tuberculin, with a second record, in which he gives a detailed account of twenty-eight cases thus treated. In his earlier publication he assumed that the success of this treatment depended on protein shock, but he also believed that a specific bacterial protein, such as tuberculin, was much more effective than the various polyvalent protein preparations on the market. In his hospital practice he has given subcutaneous injections of one of these preparations (cibalbumin), and has always observed the usual reaction—headache, pain, and redness at the site of injection. In spite of this reaction there was no improvement in the asthmatic state. But in most cases great improvement was effected when he gave Hoechst's albumose-free tuberculin. The initial dose was 0.0001 gram, and the final dose was 0.10 gram. Tuberculins made from bacilli of the bovine and avian types proved to be inert. The author also used Hoechst's tuberculin T.O.A.—the preparation with which Storm van Leeuwen has achieved

his successful results in asthma—he recommends it in those cases in which a markedly positive Pirquet reaction suggests that the patient is unusually sensitive to tuberculin. As tuberculin does not keep well after dilution, each dilution was made at the time of the injection or only a few days before it. The tabulated and detailed records of the twenty-eight cases show that, if a period of three months' freedom from attacks be regarded as evidence of improvement, nineteen of the patients, or 68 per cent., showed improvement. The remaining 32 per cent. were unaffected by the treatment. The author points out that these results coincide fairly closely with Storm van Leeuwen's results in about 300 cases of asthma treated with tuberculin, of which 78 per cent. showed recovery or marked improvement, whereas 22 per cent. showed no change.

259. Sanocrysin in Surgical Tuberculosis.

P. COKKALIS (*Med. Klinik*, January 7th, 1927, p. 17) remarks that sanocrysin has hitherto been used almost excessively in pulmonary tuberculosis. Chlevitz and Ulrici made trial of it in surgical tuberculosis, but their results were not encouraging, and only Achelis has seen good effects from sanocrysin in cases of this kind. Cokkalis employed sanocrysin in 11 male cases of surgical tuberculosis, a total dosage of 4.5 to 5.5 grams being injected intravenously in the course of five to six weeks. The dose at first was usually 0.05 gram and was gradually raised to 1 gram. The interval between each injection varied with the severity of the reaction. Fever, which was usually of short duration, was noticed during the treatment in almost every case. In two cases there was a *morbilliform* eruption. The greatest risk in sanocrysin treatment is that of damage to the kidneys, death due to uraemia being frequent according to Jansen. In 2 cases alarming symptoms of cardiac weakness followed by diarrhoea and sweating compelled Cokkalis to discontinue the treatment. Of the 11 patients 2 had to be dismissed from consideration as, though no change was observed, they had been under treatment only a short time; 3 were unaffected, 3 showed considerable aggravation of their condition, and the remaining 3 clinical improvement. The author adds that these results are not encouraging, and do not justify a belief in the curative action of sanocrysin in surgical tuberculosis.

Disease in Childhood.

260. Microcephalic Children.

T. BRUSHFIELD and W. WYATT (*Brit. Journ. Child. Dis.*, October-December, 1926, p. 265), as the result of observations at the Fountain Mental Hospital, report that the characteristic features of the true microcephalic skull are (1) marked recession of the frontal and parietal regions, (2) flattening of the occipital region, (3) a prominent nose and receding chin, causing a bird-like appearance, and (4) two marked angles, one at the centre of the face and the other at the top of the head. In infancy the head is not so small in relation to the body, but during the first six months of life there is no rapid growth, and the microcephaly, which was at first not evident, soon becomes obvious. All grades of mental defect occur, but most of the authors' cases belonged to the low grade imbecile or idiot groups. The following data were compiled from cases where histories were obtained. In 53 families 8 were only children, 23 were first-born, and 3 was the average number in the family. In 52 cases the average age of the father was 43.5 and of the mother 36.5. Of 70 patients 9 were blind, 20 were subject to convulsions, and the majority showed some definite loss of power in the lower extremities, while 30 died from various causes, the average age at death for males being 3, and for females 4.7 years.

261. Tuberculous Empyema in Young Children.

P. LAMOTHE and H. BERNARDOU (*Gaz. hebd. des Sci. Méd. de Bordeaux*, November 14th, 1926, p. 1727) report a case in a male infant, aged 22 months, following measles, in whom the disease at first assumed the form of a protracted pneumonia until thoracocentesis was performed and a sero-fibrinous exudation evacuated. After transient improvement the temperature rose again and severe gastric and respiratory symptoms developed. The pleural effusion was then found to be purulent. At the present time, although the child appears to be in good health, the remote prognosis is unfavourable, owing to the persistence of an incurable tuberculous lesion of the pleura. The rarity of empyema in pulmonary tuberculosis in the child is illustrated by the fact that Sainton was able to collect only three undoubted examples in his thesis. Tuberculous empyema may be primary, or secondary to an active pulmonary tuberculosis or a spontaneous or artificial pneumothorax. In the present case the pleurisy was primary.

262. Renal Tuberculosis in Children.

ARMAND-DELILLE (*Journ. de Méd. de Paris*, November 22nd, 1926, p. 971) states that the kidney may be the only localization of tuberculosis in children, or may be associated with multiple tuberculous lesions elsewhere. There is usually a long latent period at first, in which an exact diagnosis cannot be established unless a systematic examination is made. The first symptom is often a sudden haematuria, which may be profuse, constituting a "renal haemoptysis," or so slight as only to be discovered on microscopical examination. In other cases the onset is characterized by simple albuminuria, which is either continuous or intermittent. More rarely vesical symptoms are observed in the form of pain in the bladder, pollakiuria, and pain on micturition. A symptom peculiar to children is reflex incontinence of urine, which, in a hitherto clean child, should always suggest the possibility of renal tuberculosis. If treatment is not employed at the onset the renal pelvis becomes invaded, and the dominating symptom is then pyuria accompanied by pollakiuria and pain on micturition. In the absence of treatment death always ensues, either from cachexia with signs of amyloid degeneration or from tuberculous meningitis. As regards the diagnosis, it will often be necessary to resort to cystoscopy and separation of the urine from each kidney to see if there is a renal lesion. Injection of lipiodol into the renal pelvis, followed by *x*-ray examination, may be of service. Treatment need not always be surgical, especially if the diagnosis has been made early. In such cases physiotherapy, especially heliotherapy, in association with the ordinary hygienic, climatic, and drug treatment, will very often be sufficient to bring about a cure. In late cases with advanced but unilateral lesions nephrectomy must be performed.

263. Dietetic Treatment of Diabetes in Childhood.

W. M. BARTLETT (*Amer. Journ. Dis. Child.*, November, 1926, p. 641) records the result of his investigation to determine the actual minimum protein requirement in children. He defines this as that amount of protein which will establish a positive nitrogen balance, prove adequate for growth in stature, promote natural development, and allow the child to gain weight at a normal rate. Six diabetic children, ranging from 4 to 14 years in age, were studied with this view, four being treated without insulin, while in two cases the condition was so severe that insulin was necessary to ensure complete utilization of maintenance diets. The author finds that the protein requirement of children varies inversely with the age and is directly proportional to the rate of growth. It also varies inversely with the caloric intake. Provided that their caloric requirement is fulfilled, and that the diet is adequately chosen from foods rich in vitamins, children aged from 4 to 14 require 1 to 0.6 gram of protein per kilogram of body weight, but evidence of protein starvation may be absent in diets even lower in protein. These figures are considerably below those estimated by Holt—namely, 4 grams of protein per kilogram of body weight in infancy and childhood to 2 grams in adolescence. The author also observes that the protein requirement of children bears no relation to the fatty acid glucose ratio, provided it is compatible with a persistent absence of ketosis.

Obstetrics and Gynaecology.

264. Foetal Injury due to X-ray Treatment.

W. FLASKAMP (*Zentralbl. f. Gynäk.*, January 1st, 1927, p. 14) defines two grades of *x*-ray treatment of the ovaries; in the first, "temporary sterilization," the dose given is strong enough to produce amenorrhoea and sterility for some time; in the second, "weak ovarian radiation," amenorrhoea is not produced. Ovarian function is not arrested by the latter method; ripe ova may be severely damaged, and, as conception is possible, there is risk of damaged offspring. Flaskamp states that although this view is generally accepted, nevertheless weak radiation is frequently recommended for inflammatory conditions and sterility, and he advises strongly against it. Opinions differ as to temporary sterilization; the first conception after the amenorrhoea frequently ends in abortion. This may be caused by the condition necessitating *x* rays, as in the case of myoma, or by direct injury being inflicted on the uterine muscle by the treatment, or by atrophic changes occurring during the amenorrhoea. Abortion is commonest when conception follows quickly on the amenorrhoea; subsequent pregnancies are usually normal. As regards the children conceived after temporary amenorrhoea, about 200 pregnancies have been observed, and in all these the children were healthy or not damaged by the treatment. This is considered to afford evidence that the ovary completely regains its function after the period of amenorrhoea. Some cases of disease or abnormality have been ascribed to

such treatment, and the author thinks it is regrettable that more details of such cases and their histories have not been published so that other causes and coincidences might be eliminated. Wintz holds that the ovary regains its full function after the period of amenorrhœa. The Erlanger clinic found a fundamental difference between the effect of radiation on the ripe and on the primordial follicle which has still to develop. The technique of temporary sterilization is difficult and should be performed only by an expert. The author uses it in carefully selected cases of severe inflammation of the adnexa when menstruation is retarding recovery, but not as a general panacea or contraceptive. He adds that conception should be avoided in the period between radiation and onset of amenorrhœa, and that any pregnancy that occurs should be terminated, for it is in such cases that a damaged ovum may be fertilized.

255. Etiology of Dysmenorrhœa.

H. BECKWITH WHITEHOUSE (*Journ. Obstet. and Gynaecol. Brit. Empire*, Winter No., 1926, p. 607) reports the results of [illegible] pathology and causation of dys- [illegible] during the past two years. The [illegible] details in patients were recorded over a series of several consecutive periods, examinations of the lochia were made in cases with and without pain, and the clinical symptoms were correlated with physical pelvic signs, especially with regard to the severity of the pains. Non-conceptional dysmenorrhœa is regarded as a clinical and pathological entity in contradistinction to menorrhagia, which merely implies painful menstruation as a clinical concomitant of a variety of lesions. It was found that the expulsion of tissue in the shape of flakes, plaques, or casts was always associated with the condition, the severity of the pain being dependent upon and proportionate to the degree of denudation of the endometrium and to the size of the fragments expelled. Only in a secondary sense was the pain found to be dependent upon the uterine conformation or the nervous control of the individual. Examination of the lochia showed that the tissue expelled consisted usually of hyperplasic decidua with or without fibrin, the proportion of each constituent varying in different cases and being one of degree only. The author states that the so-called membranous dysmenorrhœa, or exfoliative endometritis, is merely an extreme degree of a comparatively common pathological condition of the menstrual decidua. He considers hyperplasic decidua as being a reflection of excessive luteum activity or high vitality of the ovum, and that non-conceptional dysmenorrhœa is an exaggeration of the positive menstrual phase; it is due to precocity in decidual development and appears to imply a hypertonic sex impulse, which tends in due course to become exhausted. Treatment should aim at initiating an early negative phase by inducing degeneration of the corpus luteum, uterine operations being only palliative for the relief of the associated pain. Theoretically inhibition of the positive menstrual phase might be achieved by inhibition of ovarian activity with *x* rays or radium, or degeneration of the corpus luteum might be produced by extracts of the early developing ovum.

256. Salpingitis Following Ozoena.

H.-E. SCHEYER (*Zentralbl. f. Gynäk.*, December 11th, 1926, p. 3186) records a case of bilateral pyosalpinx in which Friedländer's bacillus was found in pure culture. The patient, a woman aged 62, had suffered for twenty years from atrophic rhinitis, and the nasal secretion contained similar micro-organisms. Besides the pyosalpinx on each side, a pyometra and an abscess in the parametrium contained Friedländer's bacillus in pure culture. All the abscesses were chronic, but acute peritoneal symptoms occurred shortly before death, which followed a secondary streptococcal infection with general peritonitis.

Pathology.

257. Haemolysis of Bacterial Origin.

L. MULLER (*C. R. Soc. de Biologie*, January 28th, 1927, p. 189) finds that if staphylococci are grown on a medium rich in blood each colony becomes encircled by a clear zone, the margin of which follows accurately that of the colony. If only 5 to 7 per cent. of blood is added to the agar the appearance is different. Instead of a symmetrical zone of decolorization there are numerous clear spots situated around and extending for a distance of 10 to 12 mm. from the colonies. Beneath the colony the haemolysis is not uniform; the blood is riddled with little clear circles of decolorization. The number of these clear spots varies with the sample of blood; with that from normal persons about 250 to 300 are visible on a plate 15 cm. in diameter containing 60 c.cm. of medium. If the blood is centrifuged and the corpuscles and serum added separately to the agar the same result is obtained; but if the washed corpuscles alone are used, then these spots no longer appear. If the serum is heated to 55° C. before being added to the corpuscles in the agar, either no spots appear or, if a larger quantity is added, a certain number appear. If the whole blood is heated to 54° C. the number of spots decreases till after heating for thirty-five minutes, or sometimes for one hour, they completely fail to appear. If to this inactivated blood some fresh serum is added the spots again make their appearance. Filtration of the serum through a new Chamberland L2 candle has no effect, but if an old and less permeable candle is used the amount of serum necessary for the phenomenon to occur is increased. The serum can be inactivated by ether. No spots appear on a blood plate which has been incubated at room temperature, even though a good growth of staphylococci occurs. This phenomenon has been observed in 80 out of 86 specimens of human blood taken from normal persons or from patients with various diseases. Without venturing on a premature explanation the author thinks that there must be present in human blood a thermolabile filterable principle of which the development—or, better, the haemolytic activity—is conditioned by the presence of a staphylococcus.

263. The Pathogenesis of Biliary Calculi.

S. H. MENTZER (*Archives of Surgery*, January, 1927, p. 14) considers that the study of the formation of gall stones may forward the investigation of metabolic diseases, being concerned with much the same processes. He believes there are probably two types and two sources of gall-stone formation: (1) the bilirubin calcium stone containing little or no cholesterol and arising within the intrahepatic ducts, and (2) the cholesterol stone containing varying degrees of cholesterol and arising within the gall-bladder cavity. Disturbance of cholesterol metabolism of the body generally, or of the gall-bladder wall locally, with a resultant increase in the cholesterol content of bile, is probably a primary factor in the formation of gall stones. Stasis of the bile and infection of the gall bladder are not essential to stone formation, but both are usually present. Nuclei of some sort are invariably found, and are possibly essential to stone formation; in the absence of a nucleus it is possible that the ingredients of stones pass out of the gall bladder. Portions of cholesterol-laden mucous membrane lying free in the cavity of the bladder probably form the nuclei for a large portion of cholesterol stones. These conditions—namely, an increase in the cholesterol content of the gall-bladder bile, the presence of a nucleus, and a change in the *p*H value of the bile, particularly towards alkalinity—are probably the essential features of cholesterin stone formation in the gall bladder.

259. The Bromsulphalein Test of Liver Function.

E. BULMER (*Quart. Journ. Med.*, January, 1927, p. 101) records the results of a clinical study of the bromsulphalein test of liver function in 66 cases. The dose was calculated on a basis of 2 mg. of the dye per kilo of body weight, and the latter in pounds divided by 55 gives the quantity in cubic centimetres of a 5 per cent. solution to be injected into an arm vein, the process of injection occupying one minute. Thirty minutes later 4.5 c.cm. of blood were withdrawn from the vein in the other arm, but in early liver disease a sample may have to be taken after five minutes. The clear serum after centrifugalization of the coagulum was pipetted into two small test tubes, to one of which were added one to two drops of a 10 per cent. solution of sodium hydroxide to bring out the colour of the dye, and to the other a drop of 5 per cent. hydrochloric acid to clear the serum of any haemolysis. The amount of dye was then estimated by comparison with a series of standards. No local reaction followed, and in most cases no discomfort was experienced other than purgation for a few days in some very heavy persons who had received a large amount of the dye. In 20 per cent. of the cases the results were not representative of the degree of liver efficiency, and in obstructive jaundice the test appears to be one of biliary permeability and not of liver efficiency. Ten of the patients were normal healthy adults, and these varied from 5 to 45 per cent. without any obvious cause being discovered for the variation. Fourteen were not hepatic cases, ten had blood diseases, two were nephritics, five were cardiac cases, two were cases of pregnancy toxaemia, and there were three cases of obstructive jaundice, six of acute hepatitis or catarrhal jaundice, six of cirrhosis and one of doubtful cirrhosis, one of cholecystitis, one suppurative pylephlebitis, two doubtful cases of Hanot's cirrhosis, and one each of amyloid disease, haemochromatosis, and suprarenal carcinoma. Bulmer concludes that the test is simple and innocuous, but is objectionable because it depends upon colorimetry. Although every precaution was taken to exclude errors by a careful standardization of each step in the technique, the findings were variable.

CURRENT NOTES.

Some Recent Work at Headquarters.

E inclusion in last week's SUPPLEMENT of the report the proceedings of Council for February 9th displaced e usual note on some work of the week, and accordingly e present note covers a fortnight's activities at head-arters. Between February 14th and 26th four com-ttees and subcommittees met: on February 16th the lucation in Public Health Subcommittee, on February th the Ophthalmic Committee, and on February 23rd and th the Contract Practice and the Collective Research bcommittees respectively. The meeting of the Contract actice Subcommittee is dealt with in detail below. The lucation in Public Health Subcommittee was mainly occu-ed in settling the form of its report to the Public Health mmittee, while the Joint Subcommittee on Collective search was engaged in elaborating the details of a heme whose underlying principles had been decided at an rlier session. The scheme, which is of more than ordinary terest to the profession, will, it is hoped, be made public the near future. Certain points in the very heavy enda dealt with by the Ophthalmic Committee call for ecial mention here. The committee had before it a port of considerable general importance, to the effect at the Government was about to set up a departmental mmittee to consider the whole question of the desirability State registration of opticians. The committee informed e Ministry of Health that it favoured this suggestion, id appointed a special subcommittee to draw up the idence to be tendered by the Association to the proposed mmittee. A number of applications have been received cently from practitioners on the Association's list of phthalmic surgeons who wish to insert on that list the ldresses of certain hospitals at which they may be seen r insured persons. While the committee was satisfied that ch an arrangement would be extremely undesirable and id rejected all such applications, it considered it per-issible for those on the list to see insured persons at ospitals under the ophthalmic benefit scheme if it suits eir convenience to do so, provided that only the private ddress of the practitioner is inserted in the ophthalmic st. The committee also had under review the question of e propriety of reporting to approved societies upon the ondition of patients seen under the ophthalmic benefit heme. In the opinion of the committee it is undesirable at the ophthalmologist should report direct to the approved ciety on the condition of his patient. It is considered, owever, that a practitioner may add to his statement of account a footnote to the effect either that glasses have been prescribed or that the details of any treatment required have been sent to the patient's doctor.

During the fortnight under review four visits were paid to the Divisions—three by the Medical Secretary and one by the Deputy Medical Secretary. On the evening of February 15th the Medical Secretary spoke on the medical profession in South Africa at a meeting of the Lewisham Division. The meeting seemed to enjoy the somewhat informal way in which he dealt with the customs and personalities he had met with in South Africa, as a contrast to the usual medico-political address. On the evening of Saturday, February 19th, the Medical Secretary met the members of the Rugby Medical Society to discuss the desirability of constituting a Division of the British Medical Association for Rugby. There was a certain amount of hesitation, due to a fear on the part of some of those present that the Division might damage the Rugby Medical Society, which, during its short existence, had already been of real help to the local profession in bringing men together for professional and social purposes. Dr. Cox succeeded in persuading the meeting that there were many things that a Division could do that a local society could not do, and that there was no reason why the society and the Division should not work together harmoniously. Finally, it was unanimously agreed to set up a Division, the inauguration of which was formally announced in last week's SUPPLEMENT. On February 24th the Medical Secretary attended a meeting of the Horsham Division, followed by a dinner. The wide area covered by the Division and the manner in which the profession is scattered in this part of the country prevented a large attendance, but the Medical Secretary had a warm welcome from the members present, and the pleasure of meeting one or two very old friends whose official positions now preclude them from taking the active part they once did in the work of the Association. Dr. H. J. Milbank-Smith, Dr. D. Mackintosh of Worthing, and the Chairman of the Urban District Council were also guests of the Division. On the morning of February 24th an emergency request for assistance was received from the medical staff of the Dorset County Hospital, who were in a position of great difficulty owing to the action of the committee of management of the hospital in altering certain rules affecting professional matters, without prior consultation with the medical staff. The Deputy Medical Secretary went to Dorchester the same evening, and discussed the matter with representatives of the medical staff. As a result of this discussion, when the altered rules came before the governors of the hospital at the annual meeting held next day a motion was brought forward to postpone the consideration of the proposed alterations until the Medical Committee should have had an opportunity of conferring with the committee of management.

This motion having been adopted, it may be hoped that the point at issue will be satisfactorily decided in due course.

Contract Practice Subcommittee.

The Contract Practice Subcommittee of the Medico-Political Committee met on February 23rd for the first time for nearly two years, and it had before it a memorandum explaining why there had been no meeting for so long. The chief reasons are that all Welsh contract practice questions are now dealt with by the subcommittee of the Welsh Committee, and Scottish questions by the Scottish Committee, thereby greatly reducing the central work. Further, the number of contract practice appointments has been greatly reduced since the National Health Insurance scheme came into force, and the policy of the Association as regards contract practice is now so clearly defined that questions which cannot be dealt with on general lines seldom arise, and, when they do, are seldom of such urgency that they cannot await the meeting of the parent committee. The members of the subcommittee agreed that while they had no desire to be called upon unless there was sufficient business to justify busy men being brought to London, they considered that the subcommittee should continue in existence so as to be prepared to deal with any emergency business that may arise.

Prizes for Essays by Medical Students, 1928.

The Council of the British Medical Association proposes to award in March, 1928, prizes of £10 each for the best essays by final-year medical students on "What are the evidences of heart failure? Describe signs and symptoms of any three cases personally examined." One prize will be given in each of the following groups of medical schools:

GROUP 1.—University of Aberdeen; University of St. Andrews (University College, Dundee).

GROUP 2.—Queen's University of Belfast; University of Dublin (Trinity College); National University of Ireland (University College, Cork; University College, Dublin; University College, Galway); Royal College of Surgeons in Ireland (Schools of Surgery).

GROUP 3.—University of Birmingham; University of Bristol; University of Wales.

GROUP 4.—University of Durham; University of Leeds; University of Sheffield.

GROUP 5.—University of Edinburgh; School of Medicine of the Royal Colleges.

GROUP 6.—University of Glasgow; Anderson College of Medicine; Queen Margaret College School of Medicine for Women; St. Mungo's College.

GROUP 7.—University of Liverpool; Victoria University of Manchester.

GROUP 8.—London: Charing Cross Hospital Medical School; King's College Hospital Medical School.

GROUP 9.—London: Guy's Hospital Medical School; London Hospital Medical College.

GROUP 10.—London: London (Royal Free Hospital) School of Medicine for Women; University College Hospital Medical School.

GROUP 11.—London: Middlesex Hospital Medical School; St. Mary's Hospital Medical School.

GROUP 12.—London: St. Bartholomew's Hospital Medical College; St. George's Hospital Medical School.

GROUP 13.—London: St. Thomas's Hospital Medical School; Westminster Hospital Medical School.

GROUP 14.—Medical Schools in the British Empire outside the United Kingdom.

The prizes will be awarded to the authors of the essays deemed to be the best sent in from the respective groups, but if no essay received from a group is considered deserving of a prize no prize will be awarded in respect of that group. The essay, which must not exceed 5,000 words, should be clinical in nature, and must include concise notes of three cases personally observed by the student. Essays should be plainly written or typed on foolscap paper (one side only), and must reach the Medical Secretary, British Medical Association House, Tavistock Square, W.C.1, not later than January 14th, 1928. Each essay must be signed by a pseudonym only, and be accompanied by a signed and dated statement that the essay has been the bona-fide work of the competitor and that he or she has not yet passed the final professional examination, together with particulars of his or her full name, pseudonym, address, and medical school. The essays received will be adjudicated on by examiners appointed by the Council from among members of the Association not resident in the area of the particular group. The decision of the Council will be final.

Notices as to the competition have been sent to the deans of the medical schools with a request for their exhibition on the notice boards, as well as to those hospitals concerned with the education of medical students, and to the honorary secretaries of the Divisions and Branches of the Association in whose areas the respective schools are situated.

Subject for Essay, 1929.

The subject for the essay for similar prizes to be awarded in March, 1929 (essays to be received by mid-January, 1929), will be: "The symptoms and sequelae of encephalitis lethargica, with their appropriate treatment." Further particulars of the 1929 competition will be announced in due course.

The Association's Annual Handbook.

Copies of the *Annual Handbook of the British Medical Association* for 1926-27 are available for members and others. Primarily intended as a book of reference for honorary secretaries and other workers of the Association, the *Handbook* is also of interest and assistance to all members. The new edition has been completely revised. It contains the decisions of the Representative Body of the Association on matters of policy; information as to the constitution of the Association; particulars of the new London and Scottish Houses of the Association; information as to the BRITISH MEDICAL JOURNAL, the circulation of which is now over 36,000 copies weekly, and other publications of the Association; and lists of the Council, central committees, officers, and officials of the Association. It also contains a great deal of general information as to the work of, and facilities offered by, the Association. Copies of the *Handbook* can be had by members, *gratis* and post free, on application to the Medical Secretary, British Medical Association House, Tavistock Square, London, W.C.1. To non-members the book is on sale at 3s. 6d. (post free 3s. 9½d.).

Meetings of Branches and Divisions.

EDINBURGH BRANCH.

Winter Clinical Meeting.

THE winter clinical meeting of the Edinburgh Branch, with other Scottish Branches, was held in the Royal Infirmary, Edinburgh, on February 25th, on the same lines as in former years, and attracted a good attendance.

Museum demonstrations were arranged in the pathological department of the Royal Infirmary, and included remedial exercises; illustrations of treatment by diathermy; endoscopy; external diseases of the eye; and apparatus for treatment by ultra-violet rays. Pathological specimens displayed included tumours of the kidney; simple and malignant gastric lesions; intestinal tuberculosis; x-ray photographs illustrating resolution in chronic pneumonia and empyema in childhood; obstetrical and gynæcological conditions. In the afternoon clinical demonstrations were given. Dr. COMRIE described the treatment of general paralysis by artificial malaria, and Mr. BATCHELOR showed a case of keratodermia blennorrhagica in a man, aged 30, and the extensive deformities produced by congenital syphilis in a boy, aged 11. Two cases of fracture of the carpal scaphoid were shown by Mr. PATERSON BROWN, and Miss HERZFELD showed a case of interscapulo thoracic amputation for osteo-sarcoma of the humerus in a boy, aged 8, and a supracondylar fracture of the humerus in a boy, aged 7. Dr. MCNEIL demonstrated the treatment of empyema by repeated aspiration, and Mr. COCHRANE illustrated the orthopaedic correction of multiple deformities of the spine and limbs in chronic arthritis. Mr. J. J. M. SHAW presented a case of muscle transposition in complete one-sided facial paralysis, and Mr. NORMAN DOTT demonstrated the results in two cases of the trans-sphenoidal operation for pituitary adenoma, and two cases of complete irreducible intussusception.

Branch Dinner.

Sir ROBERT PHILIP, president of the Branch and President-Elect of the British Medical Association, presided over the dinner in the evening at the Scottish House of the Association. The attendance was particularly good in view of the prevailing epidemic of influenza, and a very pleasant evening was spent. The toast of "The British Medical Association" was proposed by Baillie NASMYTH, and Dr. J. R. DREVER, Scottish Medical Secretary, replied. Dr. WOODBURN MORISON proposed the health of "The Guests," and replies were made by Dr. G. CLARK TROTTER, who had been attending the first annual meeting of the Industrial Health Education Society, of which he has been appointed honorary secretary; by Dr. HUGH MILLER, chairman of the Scottish Committee of the British Medical Association; and by Dr. J. E. MONRO, president of the Royal Medical Society of Edinburgh.

WESTMINSTER AND HOLBORN DIVISION.

Discussion on Sport: Its Use and Abuse.

A DISCURSIVE and sometimes amusing debate on sport took place at a dinner meeting of the Westminster and Holborn Division of the British Medical Association on February 24th. The claims of boxing, fencing, golf, motor-racing, and yachting were warmly advocated by speakers who excelled in these various directions, and who were called upon strictly in the alphabetical order. But the sympathies of the whole gathering went out to one member, who, by an unfortunate mistake, had prepared a careful contribution on a different subject, which had to go undelivered; in the notice sent to him the first letter in the title of the subject under discussion had been dropped!

Mr. A. L. W. WHITEHOUSE, the Chairman of the Division, in opening, regretted that medical men, in giving advice to their patients, should so frequently put them off their sports. A man might follow a sport which it was injudicious for him to continue, but in that case an endeavour should be made to put him on to some other sport which could be enjoyed without aggravating his condition.

Dr. ADOLPHE ABRAHAMS said that at first sight it seemed as if the heart must necessarily suffer from the violent exercise which athletics entailed. Yet cardiologists were unanimous in affirming that a healthy heart could not be damaged by any exercise of which a human being was capable. It was curious that the heart during violent exercise actually contracted rather than dilated. The alleged heart-strain which boys—oftener boys than men—suffered subsequently from diseases of the chest, but it was to they were nearly always boys with an unstable vasomotor system, and the condition from which they suffered was that of being "run out." As for the lungs, it was affirmed that a good many men who had engaged in violent exercises suffered afterwards from pulmonary tuberculosis, or, if they were attacked by lobar pneumonia, had it more severely than ordinary people. It might appear from statistics that a large preponderance of rowing men suffered subsequently from diseases of the chest, but it was to be remembered that the vast majority of rowing men were very tall, and tall men were much more susceptible to diseases of the lungs than men of compact build. He did not believe that athletes in comparison with other tall men suffered unduly. It had also to be remembered that often the tuberculous subject had a flair for athletics. It had been asserted that rowing men in particular, after a very severe training, exhibited albuminuria and sometimes casts in the urine. His own observations had been on Olympic runners, among whom he had found albuminuria remarkably inconspicuous even after the most severe efforts. He suspected that the vasomotor question was again at the bottom of the trouble. In boys or very young men the vasomotor system was often comparatively unstable, and the albuminuria found was akin to the postural albuminuria with which they were familiar in other circumstances in athletics. There was no evidence that athletics, at any rate, had any permanent effect upon the kidneys. Such albuminuria as there might be was the result of temporary congestion. Athletics had also been accused of ill effects upon digestion, but athletes frequently had the most fantastic ideas about dietetics, and a good deal of their digestive disturbance resulted, not from their athletics, but from the following out of these ridiculous notions. A good many runners did suffer from indigestion, but he thought the great majority of digestive disturbances which had been assigned to organic disease were nothing more than manifestations of nervous dyspepsia. Finally, the production of a neurasthenic condition was sometimes laid to the account of athletics, but the athlete was apt to be a neurotic person worried about his physical condition in relation to exercise, and it was possibly just a misconception of that neurotic attitude which had earned for athletes a reputation for neurasthenia. Accidents were concomitants of any sport, but, apart from these, sport could not be assailed on account of any health impairment, certainly not of heart impairment, either immediate or remote.

Mr. IVOR BACK, who was asked to speak as one who had advised the Cambridge crew, divided sport into two categories—the sport of the young man, which was simply an expression of his enthusiasm and energy, and the sport of the elderly, which was chiefly a corrective for the liver. Rowing certainly could not be impeached for permanent impairment of health. If the after-history of the men who had got their blue for rowing were investigated it would be found that many of them had died in deaneries at the age of 91, or had continued to dispense justice from the bench to a very advanced age. There was, of course, some effect upon the abduction muscles caused by rowing, but the average rowing man, at first glance, would not be taken for an athlete at all. He had spindle legs, no thigh muscles, tremendous muscles in his back, a good thorax, and hands like those of a coal-heaver! Whether the rowing produced the type or the type produced the rowing he had never been able to decide. He thought that of all the sports he knew rowing did less harm than any.

Dr. J. D. BENJAFIELD put in a word for motor-racing, though he admitted that a doctor who indulged in this sport might be supposed to live a Jekyll and Hyde existence. Motorists might be divided into three classes: those who used the car as a necessary evil; those who combined an appreciation of its utility with an interest in the well-being and performance of their car, and to whom an occasional burst of speed brought a real thrill and enjoyment; and, finally, those who took their car at all times as fast as they could take it, regardless of their own safety or that of other people—in a word, the "road-hogs." Medical men very generally belonged to the second class, and found it a good thing to alternate spells of work with a brisk drive, which gave their minds a chance to recover. Sometimes, however, the road would not furnish all that the motorist wanted, and then there was real enjoyment, exhilaration, and a new perspective to be gained by resorting to the racing track.

Mr. P. G. DOYNE advanced the claim of fencing, a sport which could be pursued vigorously or gently, and in which efficiency could be kept up until old age. It was a sport also in which women could excel, almost, not quite, as much as men. He knew of no disability which would rule out fencing. Even excellent eyesight was not necessary. What was most important in any sport from the point of view of vision was not actual acuity, but good balance of the two eyes. So little necessary was acute sight in all these rapidly co-ordinated acts that it was amazing what people with poor eyesight could achieve.

Dr. PETER FOWLIE acclaimed the "royal and antient game," which could be continued even into old age, and which had all the uses of a sport, and not one abuse, though he rather thought that abuse was likely to be manufactured as a result of organized club competitions and "pot hunting." There was no disease for which golf was not good. He had seen a man with one of the worst forms of valvular disease, not merely come to no harm on the links, but actually kept alive on account of his interest in the game and of the fresh air into which it brought him.

Major M. P. LEAHY, speaking of boxing, said that even in middle age sparring offered great help to invalids, given, of course, a partner who understood his opponent. For neurasthenia there was nothing like "a good sweat and the swapping of a few punches."

Dr. E. MERVYN THOMSON said that, after all, the greatest change of environment was afforded by yachting, though it was not advisable for any man not sound of heart and lung, because there arose in yachting at any moment emergencies which taxed the strength to the utmost. He denied that it was an expensive sport—at least for the cruising yachtsman, owner of a 5-tonner or a 10-tonner, which he worked himself. Yachting was also advocated by another speaker, Dr. T. H. HILLIARD, who said that some thought there was risk of exposure in sea sailing, but for his own part he had been in Southampton Water often in a gale and had never caught cold, whereas he had done so on fresh water.

In the course of further discussion, Dr. R. E. STUART-WEBB put in a word for football as inculcating the team spirit, which was one of the greatest qualities sport could foster. But for women he deprecated football, as also boxing and long-distance running. Dr. G. E. ORME said that often it was recommended that boys, on account of some supposed cardiac weakness, should not be allowed to take part in games at school. He thought that in 90 per cent. of such cases the boys might be allowed to play games, to their great benefit. Dr. M. A. CASSIDY said that the only people he had seen injured by athletics were the very young and the elderly. He protested against the fetish that athletics to be successful must result in a violent perspiration.

WEST DORSET DIVISION.

AT a meeting of the West Dorset Division, held on February 22nd at Blandford, Professor G. E. GASK, C.M.G., D.S.O., F.R.C.S., director of the Surgical Professorial Unit at St. Bartholomew's Hospital, delivered a most interesting and informative British Medical Association Lecture, entitled "The therapeutic value of operations for gastric ulcer." The lecture was illustrated with lantern slides. At the close Professor Gask was warmly thanked and many members asked questions, to which he replied.

The meeting then adjourned to Dr. Kenneth Wilson's house, where Dr. WILSON showed a young woman with dislocation of the distal end of the left clavicle. Afterwards an excellent tea was provided by Dr. and Mrs. Wilson.

CHICHESTER AND WORTHING DIVISION.

A MEETING of the Chichester and Worthing Division was held at the Hospital, Worthing, on February 16th, when Dr. H. J. M. MILBANK-SMITH presided.

After tea, which was served in the Board Room at 5 p.m., the meeting proceeded to the out-patient department, where a number of clinical cases was demonstrated by Dr. GIBSON. The cases were mostly the result of injury, and included two cases of fracture of the lower jaw, Pott's fracture, ankylosis of left shoulder-joint, acquired faulty articulation of the jaw, and an incisional hernia of the abdominal wall repaired by catgut sutures. An interesting

discussion followed. Thereafter Dr. F. HINDS read a most interesting paper on "Recollections of forty years' practice."

The thanks of the meeting to Dr. Gibson and Dr. Hinds were voiced by Dr. MORRIS and Dr. LEEDS HARRISON, and a vote of thanks was passed to the board of directors for the use of the hospital and to the matron for preparing the tea.

The meeting then adjourned to the Burlington Hotel, where twenty-three members sat down to dinner. A short toast list was gone through.

Association Notices.

BRANCH AND DIVISION MEETINGS TO BE HELD.

CAMBRIDGE AND HUNTINGDON BRANCH.—A meeting of the Cambridge and Huntingdon Branch will be held at Addenbrooke's Hospital, Cambridge, to-day (Friday, March 4th), at 2.30 p.m. Agenda: Nomination of representative on the committee for the County Midwives Acts; specimens by Dr. J. R. C. Canney: (1) interstitial pregnancy, (2) malignant hydatidiform mole, (3) multiple echinococcal cysts of pelvis, etc., (4) special vaginal forceps; by Mr. H. B. Roderick: Perirenal abscess; by Dr. G. M. Tanner: The influence of castor oil on the course of acute appendicitis—a statistical survey.

GLASGOW AND WEST OF SCOTLAND BRANCH: DUMBARTONSHIRE DIVISION.—A dinner of members of the Dumbartonshire Division will be held in the North British Station Hotel, Queen Street, Glasgow, on Wednesday, March 9th, at 7.30 p.m., when Dr. W. B. Armstrong (Lenzie) will take the chair. Tickets 15s., payable in advance or at the dinner.

GLASGOW AND WEST OF SCOTLAND BRANCH: LANARKSHIRE DIVISION.—A meeting of the Lanarkshire Division will be held at the Masonic Hall, Hamilton, on Tuesday, March 8th, at 8.30 p.m., when a lecture arranged by the Monklands Medical Society will be given by Dr. J. Hume Patterson, county medical officer of health, on "Provisions for a pure milk supply."

GLOUCESTERSHIRE BRANCH.—A meeting of the Gloucestershire Branch will be held at the General Hospital, Cheltenham, on Thursday, March 10th, at 6 p.m.; supper at the Cadena Café after the meeting. Members desiring to be present at the supper are asked to notify the honorary secretary. Agenda: (1) Adjourned discussion on carcinoma of the stomach; (2) Dr. J. B. Davey: "Some interesting blood pictures"; (3) Mr. Norman H. Pike: "The significance of optic neuritis."

KENT BRANCH.—The quarterly meeting of the Kent Branch will be held at the Saracen's Head Hotel, Ashford, on Friday, March 11th, at 3 p.m. The President (Dr. H. M. Raven, Broadstairs) will open a discussion on poliomyelitis, to be followed by Dr. A. M. Watts (medical officer of health, Broadstairs). Dr. Reginald Miller (St. Mary's and Great Ormond Street Hospitals) will also be present and take part. Luncheon has been arranged at the hotel, at 2 p.m., for 3s. 6d. each. Members intending to be present are asked to send a postcard to the management by Wednesday, March 9th.

LANCASHIRE AND CHESHIRE BRANCH: HYDE DIVISION.—At the meeting of the Hyde Division to be held in the Dukinfield Town Hall on Thursday, March 17th, at 8.30 p.m., Dr. Robertson will deliver his presidential address.

METROPOLITAN COUNTIES BRANCH: CITY DIVISION.—The annual fancy dress dance of the City Division will be held on Thursday, March 24th, in the Great Hall of the British Medical Association Headquarters, Tavistock Square. It is hoped that members will make up parties. First class band, and refreshments by Gunters, Ltd. Dancing, 8.30 p.m. to 1.30 a.m. Ticket, inclusive price 8s. Cars may be garaged in the Association garage. Tickets may be obtained from Dr. Harold Latham, 2, Hemingford Road, Barnsbury; Dr. G. Clark Trotter, 2, Tyndale Place, Upper Street, Islington; and from the honorary secretary, Dr. Worley, 43, De Beauvoir Road, N.1.

METROPOLITAN COUNTIES BRANCH: HAMPSTEAD DIVISION.—At the meeting of the Hampstead Division, to be held on Thursday, March 10th, at 8.30 p.m., Dr. W. J. Pearson, physician to the Hospital for Sick Children, will give an address on "Chronic respiratory infections in childhood."

METROPOLITAN COUNTIES BRANCH: LEWISHAM DIVISION.—A clinical evening will be held by the Lewisham Division at the South Eastern Children's Hospital, Sydenham, on Tuesday, March 15th.

METROPOLITAN COUNTIES BRANCH: ST. PANCRAS DIVISION.—A meeting of the St. Pancras Division will be held in the British Medical Association House, Tavistock Square, W.C.1, on Tuesday, March 8th, at 9 p.m., when Mr. A. G. Timbrell Fisher, *M.C.*, will deliver a lecture on "Manipulative surgery."

METROPOLITAN COUNTIES BRANCH: SOUTH MIDDLESEX DIVISION.—A meeting of the South Middlesex Division will be held at St. John's Hospital, Twickenham, on Wednesday, March 9th, 8.15 p.m., General business. 8.30 p.m., Discussion: "Treatment of cancer by non-operative means," to be opened by Dr. J. B. Cook, medical superintendent, West Middlesex Hospital.

METROPOLITAN COUNTIES BRANCH: WILLESDEN DIVISION.—A meeting of the Willesden Division will be held at the Willesden General Hospital, Harlesden Road, on Wednesday, March 16th, at 9 p.m. Agenda: Correspondence, etc.; Dr. A. Hope Gosse (St. Mary's Hospital) will give an address on "Clinical disorders of the heart"; election of representative and deputy representative for Annual Representative Meeting at Edinburgh.

NORFOLK BRANCH.—A meeting of the Norfolk Branch will be held at the Norfolk and Norwich Hospital on Wednesday, March 16th, at 3.30 p.m., when the President, Dr. W. M. Fisher, will take the chair. Dr. Sydney H. Long will give a demonstration, with cinematograph films, on "Manifestations of syphilis and gonorrhoea." Tea will be served at 4.45.

NORTH OF ENGLAND BRANCH.—A scientific meeting of the North of England Branch will be held at Greenbank Hospital, Darlington, on Thursday, March 17th:—2.30 p.m., Mr. A. Thacker Neville: Laryngology and ophthalmology in relation to general practice; 3 p.m., Mr. R. J. Willan: Some common but obscure cases of acute abdominal pain; 3.30 p.m., Dr. George Hall: Minor endocrine defects; 4 p.m., tea; 4.15 p.m., Mr. H. C. Pearson: Modern electro-therapeutics; 4.45 p.m., Mr. D. S. Falconer: Food disorders in infancy. The annual dinner of the Branch will be held at the Central Station Hotel, Newcastle-on-Tyne, on Thursday, March 17th, at 7 for 7.30 p.m.; the President of the Branch, Mr. W. S. Dickie, F.R.C.S., will take the chair. Tickets 10s. 6d. Applications for seats should be made to Mr. Norman Hodgson, honorary secretary, 7, Windsor Terrace, Newcastle-on-Tyne, before March 14th.

NORTH OF ENGLAND BRANCH: NEWCASTLE-ON-TYNE DIVISION.—*Mr. H. S. Elphick, M.R.C.V.S., will give a lecture on March 10th, at* 8.30 p.m., in the Library of the Royal Victoria Infirmary, on "Pregnancy and parturition in veterinary practice." The Division is holding a reception and dance with cabaret about the end of March or beginning of April. The arrangements are in the hands of a subcommittee, and details will be announced shortly.

NORTH OF ENGLAND BRANCH: SUNDERLAND DIVISION.—A scientific meeting of the Sunderland Division will be held at the Royal Infirmary Sunderland, on Wednesday, March 16th, at 8.15 p.m. *Mr. F. C. Pybus, M.S., F.R.C.S., will give an address on* deformities. All members of the Division are invited to be present.

NORTHERN COUNTIES OF SCOTLAND BRANCH.—A clinical meeting of the Northern Counties of Scotland Branch will be held at the District Asylum, Inverness, on Friday, March 11th, at 3 p.m.

SOUTHERN BRANCH: PORTSMOUTH DIVISION.—The next meeting of the Portsmouth Division will be held at the Queen's Hotel, Southsea, on Thursday, March 10th, at 9.30 p.m., when Sir John Collie, C.M.G., M.D. vice-president of the Medico-Legal Society, *will give* an address on "Where law and medicine meet." Members are invited to bring as guests legal friends. Supper will be served at 9 p.m., and members are asked to notify the secretary as early as possible of their intention to be present, and also the names of any guests.

SURREY BRANCH; GUILDFORD DIVISION.—A special general meeting of the Guildford Division will be held on May 19th, when Professor Frederick Hobday, C.M.G., F.R.C.V.S., will open a discussion on milk. Members of the Royal Counties Veterinary Medical Association and Southern Counties Veterinary Medical Association have been invited to take part in the discussion.

SURREY BRANCH: REIGATE DIVISION.—A meeting of the Reigate Division will be held at the East Surrey Hospital, Reigate, on Tuesday, March 8th, at 8.45 p.m. Dr. Stanley Dodd will give an address on gynaecology.

YORKSHIRE BRANCH: HUDDERSFIELD DIVISION.—A British Medical Association Lecture will be given at the Huddersfield Royal Infirmary on Wednesday, March 9th, at 8 p.m., by Professor Miles Phillips of Sheffield on "Some obstetrical emergencies." Members of other Divisions are invited to attend, and light refreshments will be provided after the lecture.

YORKSHIRE BRANCH: WAKEFIELD, PONTEFRACT, AND CASTLEFORD DIVISION.—A meeting of the Wakefield, Pontefract, and Castleford Division will be held at the Bull Restaurant, Westgate, Wakefield, on Thursday, March 10th. Dr. G. W. Watson, physician to the Leeds General Infirmary, will lecture on the early signs of phthisis. Supper at 7.45 p.m. (2s. 6d.) will precede the lecture.

FABIAN MEDICINE.

IT is sometimes useful to know to what length animosity, ill-informed and unbridled, can carry the more narrow-minded of controversialists. The following is a condensed report of a recent meeting of the Fabian Society. The biased bitterness of some of the contributions may have been equalled, but can hardly have been surpassed, by the more violent theological and political controversialists of the past.

A lecture, under the auspices of the Fabian Society, was delivered by Dr. Stella Churchill at Essex Hall, Strand, on February 25th. A large audience was present, and the lecture was followed by some keen discussion. Dr. Churchill laid stress on the gaps in the present system of medical or health services, particularly the non-inclusion of dependants in the national insurance scheme, itself not very efficient, and the haphazard character of institutional provision. Various heroic attempts had been made of recent years to grapple with the situation, notably the very elaborate scheme set forth in the interim report of the Consultative Council in 1920, the not very thrilling proposals of the National Health Insurance Commission, and the Memorandum published last year by the British Medical Association, which last, she said, was a claim on behalf of the general practitioner to a share in these services. When salaried officials were first appointed the general practitioner was inclined to say that any such thing as preventive medicine was absurd, but now, when the infant death rate had been halved, and other results were apparent, he turned round and said, "These are good things. Why am I not doing *them?*" Dr. Churchill thought the claim advanced on behalf of the general

practitioner, that admission to hospital must be through his agency, a dangerous interference with the liberty of the subject. The British Medical Association, which had a way of "not arguing, but telling you," upheld the voluntary system, but from its own report many arguments against the system appeared to be obvious, notably overcrowding, understaffing, and long waiting lists. Her plea was that hospitals should be maintained as part of the organized public health service, and, with the Poor Law infirmaries, should be administered by the public authorities. As the ideal socialist state was not immediately forthcoming, she approved of paying wards, though she thought that nothing should be accepted from patients with an income of less than £200. There should be free treatment from State-aided services at clinics and in-patient institutions, and the clinic doctors, she thought, would tend more and more to follow up the supervision of children and adults in their homes. Doctors in private practice would work increasingly in teams, and, indeed, she looked forward to the day when one-man practices would not be allowed. No doctor should be expected to work day and night. What was the value of any attendance by a doctor who had not been "out of his clothes" for thirty-six hours? She would have, say, a team of four doctors working together, with proper arrangements for night duty. She admitted certain drawbacks to making medicine a civil service, notably the multiplication of forms to be filled up, but this was not a necessary concomitant, and she was sanguine enough to look forward to State subsidies without State control. Yet in reply to a question immediately asked as to what guarantee there would be for an efficient standard of service in the event of obstructive and backward local authorities, she said that the Ministry of Health must impose a system of inspection, and must act in default of any local authority, just as the London County Council acted in default of a metropolitan borough council.

Mr. F. Lawson Dodd, M.R.C.S., L.D.S., who presided, spoke of a declining popular faith in regular medical practice, not entirely to be explained by the increase in quackery or cults. The socialist explanation was that this was due to the acquisitive commercial system, based upon intense individualism and competitiveness, which had invaded medical practice. The cause of disease and its treatment went out far beyond the individual sufferer, into heredity and social environment, and a statesmanlike outlook and wide observation were needed, quite beyond the possibilities of an army of forty thousand doctors working along individualistic lines with obsolete methods. It was transparently a wrong system whereby the patient suffering from disease was the person who paid the doctor. It meant that the doctor was remunerated according to the plentifulness of disease in the community—that was to say, he had a vested interest in disease. He was paid, too, according to the amount of his operative interference, whereas payment should rather be for the slowness of such interference. It was like the scale of fees laid down by the Poor Law authorities for amputations—so much for an amputation of the finger, so much more for an amputation at the elbow; at this rate the highest fee of all would be paid for killing the patient. The present system tended to draw doctors to the resorts of wealth and fashion—Bournemouth was crowded with practitioners of the highest possible skill and qualifications—to the impoverishment of poor areas. Insurance practice had reproduced a rather inferior individualist medical system, worse almost than the system it replaced. Another argument for community medical service was the growing expensiveness of treatment, which tended to prevent people seeking it, and, when they had sought it, interfered with their recovery by the worry over expenditure which they could ill afford. He praised the Swindon system of co-operative medical service, in which 16,000 persons had the advantage of a highly skilled medical staff at a cost of £31,000 a year. There was no need for a rigid State medical service from Whitehall. What was wanted was the encouragement of local experiments of the character of Swindon.

The subsequent discussion was noteworthy for a violent attack on the British Medical Association by Mr. W. A. Robson, a member of the executive committee of the Fabian Society and the editor of one of its periodicals. He described the British Medical Association as incredibly selfish and lacking in public spirit, as witness its evidence before the Royal Commission on National Health Insurance. "Whenever you see a statement on public policy by the British Medical Association you always know that they are considering the private pockets of the doctors who are their members, and are never in the slightest degree interested in the public welfare. I do not think that there is a single exception where for a quarter or half a second the British Medical Association has ever put aside the pecuniary interests of its members for the sake of an improvement in public health." He added that this showed what would come of giving the professional men a free hand so long as their professional organization was untouched.

THE DENTAL BOARD.

Warning Notice to Dentists.

AT the recent session of the Dental Board, on February 8th, Sir Francis Dyke Acland presiding, the Board made certain amendments to bring the wording of its Warning Notice into conformity with that of the General Medical Council. The notice is of an omnibus character, and calls attention to the fact that convictions for felony or misdemeanour, also certain forms of professional misconduct, including the employment of unregistered assistants and covering, the contravention of the Dangerous Drugs Acts and the regulations made thereunder, advertising and canvassing, and the use of titles and descriptions suggesting status and qualifications not in fact possessed, render dentists liable, on proof of the facts, to have their names erased from the *Dentists Register*. In an "important notice" the Board states that the publication of any announcement for the purpose of informing a dentist's patients of his change of address, or the days of his visits to a town or place, may be regarded as an advertisement if it includes the word "dentist" or any other description or engraving indicating his profession or practice. This covers the insertion of all paragraphs and notices in the press, and also the announcement of names in the trading lists of co-operative and other societies, clothing clubs, and the like, and the display of announcements at places of public entertainment. The Board only contemplates as possibly permissible the announcement of a change of address or of the days when a periodical visit is made to a locality in which there is no resident dentist through whom advice can be obtained in an emergency. It also considers that such notices as "Panel patients received here" may be held to constitute an advertisement.

Grants to Dental Schools.

The Board agreed to make a grant not exceeding £300 for the equipment of a dental museum and demonstration room at Queen's University, Belfast, and a grant of £1,500 towards the cost of movable equipment for the new dental school at Leeds, the grant in each case being accompanied by certain conditions. A report on the subject of bursaries and the method of their award is to be prepared and submitted to the Board at the May session.

National Insurance.

LONDON INSURANCE COMMITTEE.

AT the meeting of the London Insurance Committee on February 24th it was agreed to resume the work of clearing the medical register in order to eliminate therefrom the names of all persons found not to be entitled to medical benefit. It was stated that this work would take three years to accomplish, and would cost £4,500.

Ophthalmic Benefit and the B.M.A. List.

A report was presented by the Joint Consultative Committee—which consists of an equal number of representatives of the Insurance and Panel Committees—on a question raised at the previous meeting—namely, why the names of certain practitioners who had notified that they had accepted fees for ophthalmic services rendered to insured persons were not included in the British Medical Association list. The report stated that the Insurance Committee had no power to require a practitioner to take steps to have his name put on the list, and that to enable the committee to do so it would be necessary to have the regulations amended. During 1926 the number of ophthalmic cases notified to the committee was 55; fifteen practitioners were concerned, and of this number only four had not secured the inclusion of their names in the list of the Association. The number of practitioners whose names were not included in this list was therefore very small, and the general tendency was for practitioners to have their names included. The Joint Committee, after considering the matter very carefully, came to the conclusion that it could make no recommendation; at best it could only express the opinion that it was desirable that practitioners undertaking special ophthalmic services for insured persons should apply to have their names included in the list of the British Medical Association or in any other list which might be recognized by the authorities concerned. This opinion was shared by the Panel Committee, which, while not passing any formal resolution, had advised practitioners from time to time to apply for the inclusion of their names in the Association's list. The reason why another list was referred to was because the point had been put to the Joint Committee that there might be some practitioners who, for personal reasons, would not apply to the British Medical Association, and it was suggested that the Local Medical Committee might prepare a list of approved practitioners. At the same time, the Local Medical Committee could take no cognizance of the fees charged for such services.

Certification of Incapacity: Minister's Decision.

A case of some interest was reported by the Medical Service Subcommittee. An approved society had raised a question with regard to the certification by an insurance practitioner of one of its members suffering from an injury to the hand. The practitioner issued an initial certificate of incapacity, three intermediate

certificates, and a final certificate. Shortly after the initial certificate he issued a private certificate to the insured person's employer stating that she was at present unable to do scrubbing, but could do some light housework. The society complained of this action, and, on the committee holding that the practitioner had complied with the certification rules, appealed to the Minister on the point whether a practitioner might rightly certify to the approved society "incapacity for work," in the narrow and restricted sense applicable in cases where incapacity was likely to be short, and at the same time issue certificates to the employer of capacity for light work, thereby preventing the insured person from successfully prosecuting a claim for compensation, and ultimately saddling the society with a liability which normally it would not be called upon to bear. In conveying his decision, the Minister pointed out that the certificate issued to the employer was the only evidence produced in support of any allegation that the insured person was not incapable of work during the period covered by the official certificate. "The term 'incapable of work'" (the Minister's letter proceeded) "is not easy to define, but the Minister is satisfied that in the circumstances of the present case the proper criterion for the practitioner to apply was whether the patient, in view of the nature of her injury, was capable of undertaking her ordinary work, and whether it would be unreasonable to expect her to undertake any other form of work. On the facts of the case it is clear that the practitioner *bona fide* formed the opinion that the insured person was incapable of work in that sense, and there is nothing inconsistent with that opinion in the terms of the private certificate. In these circumstances I am to inform you that the Minister . . . dismisses the appeal and makes no order as to costs."

LOCAL MEDICAL AND PANEL COMMITTEES.

LONDON.

AT the meeting of the London Panel Committee on February 22nd, Dr. H. J. CARDALE presiding, Dr. George Jones was elected a member to represent non-insurance practitioners resident south of the Thames.

Claims for Payment for Anaesthetist.

The committee had before it forty claims for payment for the services of a second practitioner in administering a general anaesthetic. In six cases it was recommended that the account for the fee of one guinea be struck out, and a fee of half a guinea only be allowed, on the ground that the case was such as only to require a local anaesthetic. One of the practitioners concerned appealed against this recommendation, and appeared in person before the committee to support the appeal. He said that the case was one of cellulitis of the arm, which was incised, opened, and drained, and a second practitioner was employed to give chloroform and ether. Asked why he did not give nitrous oxide gas, he said that it was because he had not got a gas apparatus, he could offer no other reason. Dr. H. B. MORGAN moved that this practitioner be paid the full fee of one guinea. He made this amendment on the ground that the practitioner in charge of the case was the best judge of whether a general anaesthetic was needed or not. As to the length of time the operation took, he did not know that that was material. What was in every respect a major operation might be performed in a matter of seconds. Dr. NEWELL said that as a new member of the committee he was astonished to find that it could take upon itself to reduce the fee after the practitioner had given a general anaesthetic. The amendment to allow the full fee of one guinea was defeated, and this practitioner, as well as the five others who had not appealed, had to submit to the reduction. Another claim "for the services of a second practitioner in administering a general anaesthetic" was disallowed on the ground that the practitioner administered the anaesthetic himself.

Range of Medical Service.

The Local Medical Committee had before it a recommendation in respect to a case in which Form G.P.45 had been received, that excision of ganglion on wrist, necessitated by the size and painfulness of the ganglion, was a service "which did not fall within the category of services involving the application of special skill and experience of a degree and kind which general practitioners as a class cannot reasonably be expected to possess." Dr. GREGG asked why this was not allowed; he had a feeling that, taken with a good many cases of the kind which had been before the committee, it might well have been passed. Dr. G. F. STEBBING said that, on the whole, excision of a ganglion must be regarded as a very minor operation. He agreed that minor operations might be done badly, or might have complications and become difficult, but if this kind of thing was to be allowed to come under Form G.P.45 with regard to the range of medical service, it would mean that the patient would be robbed of practically all his surgical benefit. The recommendation of the subcommittee that the case be not allowed was agreed to.

Investigation of Prescribing.

A communication from the Ministry of Health was reported setting out the procedure which it has been decided to adopt in interviewing practitioners whose prescribing is in question. The practitioner is to be informed, when notified of the proposed interview, that the Panel Committee has arranged that one of its members will be prepared to attend if he desires. This procedure has been put in operation in London notwithstanding the resolution of the committee that it desired a representative to be present at every interview, the committee, however, agreed not to take any action at present, but to ask the secretary to observe the results of the procedure.

BIRMINGHAM.

A MEETING of the Birmingham Panel and Local Medical Committee was held at 151, Great Charles Street, Birmingham, on February 15th. There was a good attendance of members. In the absence of the chairman (Dr. Dain) through illness the chair was taken by Dr. BURGES. Expressions of sympathy with Dr. Dain were recorded, and also a hope for his speedy recovery. Several other members were ill and unable to attend, and the secretary was instructed to convey similar mesages to them. Notices of resignation were received from two members, and steps were taken to fill the vacancies.

Accounts for administration of anaesthetics and provision of emergency treatment were passed. In the latter case it was noteworthy that not a single claim was made upon a neighbouring practitioner. A long discussion followed with regard to the appointment by societies of private medical referees. In the end it was decided to point out to those complaining that societies were at liberty to have their own medical referees, and that if the patient's doctor disagreed with the decision he was at liberty to refer the patient to the regional medical officer.

Dr. Dain was reappointed to represent the Panel Committee on the Local Hospitals Council. A notification with regard to the increased fee payable to practitioners who supply drugs, etc., to their panel patients was received from the Insurance Committee, and approved.

Several members of the Panel Committee were appointed to be at the service of general practitioners who desired their presence at any interview with the regional medical officer on the subject of excessive prescribing. A list was sent to the Ministry of Health and to the Clerk to the Birmingham Insurance Committee. A letter from the British Medical Association headquarters referred to the establishment of a list of local ophthalmic specialists; the committee decided that it would like the name of any local applicant to be submitted to it before inclusion in the list.

It was decided to notify members that should they at any time find that chemists omitted to add "in water" to the instructions on the label when required to do so they be requested to communicate with the Secretary of the Panel Committee and bring forward concrete cases.

Correspondence.

A New Class of Panel Patient.

SIR,—I am writing on this threadbare subject hoping it may catch the eye of some of those in close touch who have to do with the working of it. For the past year I have been much concerned with the rapidly increasing numbers of the sons and daughters (particularly the latter) of well-to-do people coming on the panel.

Up to a few years ago it was usual for the daughters to remain at home and help their mothers in social and domestic duties. Now there is hardly a young lady in this neighbourhood, as soon as she reaches the age of 18 years, but must be off and doing.

In the past few weeks I have been called to attend over a dozen cases of young men and girls in not a single house with a rental of less than £100 a year, and in some considerably more. Only to-day I fixed up an operation for one of them for 50 guineas.

It seems utterly unfair that these young people, with free food and housing, should be put on the same basis as the clerk earning his four or five pounds a week with a wife and children to support. What with ante-natal, baby, and school clinics, and this latest encroachment on private practice, I am afraid the general practitioner of the future is going to have a very thin time of it if some action is not taken.—I am, etc.,

H. J. HILDIGE, M.D.

Pinner, Middlesex, Feb. 24th.

Naval and Military Appointments.

ROYAL NAVAL MEDICAL SERVICE.

Surgeon Captain P. T. Nicholls to the *Victory* for R.N. Barracks.

Surgeon Commanders F. C. Wright to the *Curacoa* and as Squadron Medical Officer; A. J. Tozer to the *Ramillies* on recommissioning.

Surgeon Lieutenant Commanders W. J. Colborne to the *Sandhurst*; J. E. Clark to the *Cambrian*.

Surgeon Lieutenants J. G. Currie to the *Beaufort*; E. C. Downer to the *Flinders*; S. G. Rainsford to the *Ramillies* on recommissioning.

Surgeon Lieutenant F. B. Quinn transferred to the permanent list.

ROYAL NAVAL VOLUNTEER RESERVE.

Surgeon Lieutenant J. B. Hutchinson to the *Victory*, additional for R.N. Hospital, Haslar, for twenty-eight days' training.

Probationary Surgeon Lieutenant E. A. Gerrard to the *Ark Royal* for twenty-eight days' training.

ROYAL ARMY MEDICAL CORPS.

Lieut.-Colonel E. P. Connolly, from R.A.M.C., to be Colonel, vice Colonel J. W. H. Houghton, D.S.O., to retired pay.

The following Lieutenant-Colonels, Regular Army Reserve of Officers, R.A.M.C., to be *Majors whilst* re-employed under Article 507 (*b*), Royal Warrant for Pay and Promotion, 1926, and relinquish the *rank of* Lieutenant-Colonel: J. L. Wood, O.B.E., and W. E. C. Lunn, M.C.

The following Captains to be Majors: H. A. Rowell, M.C., C. F. Anthonisz, and S. O. Dolan.

Temporary Lieutenant R. L. J. Le Clezio relinquishes his commission.

ROYAL AIR FORCE MEDICAL SERVICE.

Wing Commanders A. V. J. Richardson, O.B.E., to Headquarters, India, for duty as Principal Medical Officer; A. E. Panter to Air Ministry, Directorate of Medical Services, for medical staff duties; P. C. Cowtan to Headquarters, Irak; H. B. Porteous to Basrah Combined Hospital, Irak; P. D. Barling to Aden Flight.

Flight Lieutenant (Honorary Squadron Leader) F. R. Humphreys relinquishes his temporary commission on completion of service.

Flight Lieutenants (Honorary Squadron Leader) J. Valerie, O.B.E., to Inspector of Recruiting; F. W. G. Smith to No. 56 Squadron, Biggin Hill; A. Harvey to No. 14 Squadron, Palestine.

Flying Officers L. C. Palmer-Jones and T. W. Wilson are promoted to the rank of Flight Lieutenant.

Flying Officer H. C. Patterson relinquishes his short-service commission on account of ill health.

Flying Officers E. J. Mockler to No. 5 Squadron, India; M. J. Marren to R.A.F. Depot, Uxbridge; R. J. I. Bell to R.A.F. Station, Upavon; T. W. Wilson to R.A.F. British Hospital, Irak; F. B. C. L. B. Crawford to Headquarters, Irak.

The short-service commission of Flying Officer G. E. Church is antedated to February 1st, 1926, and he ceases to be seconded to the Royal Infirmary, Wigan.

INDIAN MEDICAL SERVICE.

Major-General F. H. G. Hutchinson, C.I.E., to be Honorary Surgeon to the King, vice Major-General Sir R. C. Macwatt, K.C.I.E. (retired).

The following officers are appointed substantively to be Agency Surgeons under the Government of India in the Foreign and Political Department: Majors W. J. Simpson, F. Stevenson, C. H. Smith, O.B.E., and L. H. L. Mackenzie.

Lieut.-Colonel M. N. Chaudhuri and Captain M. F. D. Graham have retired from the service.

Lieut.-Colonel D. Heron, C.I.E., an Agency Surgeon, on return from leave, is posted as Residency Surgeon, Mewar.

The services of Lieut.-Colonel J. Morison, Assistant Director, Haffkine Institute, Bombay, are placed temporarily at the disposal of the Government of Burma for appointment as Officiating Director of the Pasteur Institute, Rangoon.

Lieut.-Colonel W. O'S. Murphy to be Colonel, vice Colonel J. H. McDonald, K.H.P., retired.

The services of Major H. S. Anand are placed temporarily at the disposal of the Government of Burma.

Captains H. Aung Khin and M. A. Singh to be Majors.

The services of the following officers are placed permanently at the disposal of the Government of Bombay: Majors E. S. Phipson and A. H. Harty and Captain J. M. Shah.

The following officers have been regraded with seniority as stated against their names in substitution for all previous notifications:—Captains: R. W. H. Miller (April 10th, 1923) and G. J. Smith (April 7th, 1924). Lieutenants: T. J. Davidson (June 6th, 1923), E. G. Michelson (September 9th, 1923), D. MacD. Fraser (February 25th, 1924), and S. C. H. Worseldine (April 14th, 1924).

REGULAR ARMY RESERVE OF OFFICERS.

ROYAL ARMY MEDICAL CORPS.

Lieut.-Colonel W. B. Winkfield, having attained the age limit of liability to recall, ceases to belong to the Reserve of Officers.

SUPPLEMENTARY RESERVE OF OFFICERS.

ROYAL ARMY MEDICAL CORPS.

Lieutenant G. O. F. Roe to be Captain.

TERRITORIAL ARMY.

ROYAL ARMY MEDICAL CORPS.

Captain L. P. Marshall, M.C., late West Yorks Regiment, to be Lieutenant, and relinquishes the rank of Captain.

COLONIAL MEDICAL SERVICES.

Dr. V. J. G. Macgregor appointed Medical Officer, Medical Department, Gold Coast. Dr. J. G. S. Turner appointed Medical Officer, Nigeria. Dr. N. S. Turnbull promoted Medical Officer of Health, Sanitary Department, Nigeria. Dr. G. C. M. Davies, Senior Sanitary Officer, Gold Coast, transferred to Nigeria. Dr. J. H. McDonald transferred from Lindi to Dar-es-Salaam, Tanganyika.

VACANCIES.

ASHTON-UNDER-LYNE DISTRICT INFIRMARY.—(1) Resident Surgical Officer (male). (2) House-Surgeon. Salary at the rate of £200 and £150 per annum respectively.

BURNET: WELLHOUSE HOSPITAL.—Assistant Resident Medical Officer (male). Salary £200 per annum, rising to £250.

BARNSTAPLE: NORTH DEVON INFIRMARY.—House-Surgeon (male). Salary at the rate of £150 per annum.

BATH: ROYAL UNITED HOSPITAL.—House-Physician (male, unmarried). Salary £120 per annum.

BURNLEY UNION.—Resident Medical Officer at Primrose Bank Institution (male). Salary £200 per annum and fees for certifying mental cases.

COSSHAM MEMORIAL HOSPITAL, Kingswood, Bristol.—Resident Medical Officer (male). Salary £150 per annum.

COUNTESS OF DUFFERIN'S FUND.—Professor of Physiology for the Lady Hardinge Medical College, Delhi (female). Emolument Rs.750 a month, rising.

COVENTRY AND WARWICKSHIRE HOSPITAL.—Resident House-Physician (male). Salary £125 per annum.

CROYDON COUNTY BOROUGH.—Senior and Junior Assistant Medical Officers at the Croydon Mental Hospital, Upper Warlingham. Salary at the rate of £650 and £350 per annum respectively.

DURHAM COUNTY HOSPITAL.—Junior House-Surgeon (male). Salary £120 per annum.

EAST SUFFOLK ADMINISTRATIVE COUNTY.—Assistant County Medical Officer of Health and Medical Officer of Health for Rural District of Hoxne. Salary £625 per annum.

ENFIELD URBAN DISTRICT COUNCIL.—Medical Officer of Health, School Medical Officer and Supervisor, etc., of Maternity and Child Welfare Centres. Salary £900 per annum, rising to £1,035.

FEDERATED MALAY STATES: CENTRAL MENTAL HOSPITAL.—Second Assistant Medical Superintendent. Salary £700—£35—£1,120 per annum, with temporary allowance of 10 and 20 per cent. to unmarried and married officers respectively.

GLASGOW UNIVERSITY.—Muirhead Chair of Obstetrics and Gynaecology.

GREAT YARMOUTH COUNTY BOROUGH.—Assistant Medical Officer of Health and Assistant Tuberculosis Officer. Salary £600 per annum.

HOSPITAL FOR EPILEPSY AND PARALYSIS, Maida Vale, W.9.—Honorary Medical Officer in charge of X Ray and Electro-therapeutics.

HOSPITAL OF ST. JOHN AND ST. ELIZABETH, 40, Grove End Road, N.W.8.—Assistant Physician.

KING'S LYNN: WEST NORFOLK HOSPITAL.—Junior House-Surgeon. Salary £100 per annum.

LEEDS PUBLIC DISPENSARY.—Junior Resident Medical Officer. Salary £150 per annum.

LEICESTERSHIRE COUNTY COUNCIL.—Assistant County Medical Officer (male). Salary £750 per annum.

LIVERPOOL STANLEY HOSPITAL.—(1) House-Surgeon. (2) House-Physician. Males. Salary £100 per annum.

LONDON FEMALE LOCK HOSPITAL, 283, Harrow Road, W.—Surgical Registrar. Honorarium £100 per annum.

LONDON HOMOEOPATHIC HOSPITAL, Great Ormond Street, W.C.1.—Third Anaesthetist. Honorarium £50 per annum.

LONDON HOSPITAL, E.—Two Medical First Assistants. Salary £300 per annum.

LONDON JEWISH HOSPITAL, Stepney Green, E.1.—Medical Registrar and Out-patient Assistant. (2) Surgical Registrar. Honorarium at the rate of £50 per annum.

LONDON LOCK HOSPITAL, 91, Dean Street, W.—Surgical Registrar. Honorarium £100 per annum.

MANCHESTER: ANCOATS HOSPITAL.—House-Surgeon. Salary at the rate of £100 per annum.

MANCHESTER CITY.—Assistant Medical Officer to Public Health Department (Baguley Sanatorium), unmarried. Salary £250 per annum.

MIDDLESEX HOSPITAL, Mortimer Street, W.1.—Assistant Radiologist (Diagnostic). Salary £100 per annum.

NEWCASTLE-ON-TYNE: HOSPITAL FOR SICK CHILDREN.—Senior and Junior Resident Medical Officers. Salary at the rate of £120 and £100 per annum respectively.

NOTTINGHAM: CITY MENTAL HOSPITAL.—Junior Assistant Medical Officer (male). Salary £350 per annum, rising to £400, with additional £50 for D.P.M., and £10 for M.P.C. per annum.

OXFORD: RADCLIFFE INFIRMARY AND COUNTY HOSPITAL.—(1) House-Physician. (2) Casualty House-Surgeon. Salary at the rate of £120 per annum each.

PLYMOUTH: SOUTH DEVON AND EAST CORNWALL HOSPITAL.—(1) Resident Surgical Officer. (2) House-Surgeon. (3) House-Physician. (4) Casualty House-Surgeon (unpaid). Salary at the rate of £100 per annum for (1) and £50 per annum for (2) and (3).

PRINCE OF WALES'S GENERAL HOSPITAL, Tottenham, N.15.—(1) House-Surgeon. (2) Special [illegible] (3) [illegible]-Physician. (4) Junior House-Surgeon. (5) [illegible] Salary for (1), (2), and (3) £120 per annum, [illegible] per annum.

QUEEN'S HOSPITAL FOR CHILDREN, Hackney Road, E.2.—House-Physician. Salary at the rate of £100 per annum.

ROYAL FREE HOSPITAL, Gray's Inn Road, W.C.1 (Children's Department).—First Assistant for Out-patient and Infant Welfare Work.

ROYAL NATIONAL ORTHOPAEDIC HOSPITAL, 234, Great Portland Street, W.1.—House-Surgeon. Salary £150 per annum.

ST. JOHN'S HOSPITAL, Morden Hill, Lewisham, S.E.13.—Resident Male Casualty Officer. Salary £100 per annum.

ST. MARY'S HOSPITAL, Institute of Pathology and Research, Paddington, W.2.—Research Student. Honorarium at the rate of £200 per annum.

ST. PETER'S HOSPITAL FOR STONE, etc., Henrietta Street, W.C.2.—House-Surgeon. Salary at the rate of £75 per annum.

SALFORD ROYAL HOSPITAL.—(1) House-Surgeon attached to Orthopaedic Department. (2) House-Surgeon. Salary at the rate of £125 per annum each.

SAMARITAN HOSPITAL FOR WOMEN, Marylebone Road, N.W.1.—House-Surgeon. Salary at the rate of £100 per annum.

SEAMEN'S HOSPITAL SOCIETY, Greenwich.—House-Physician and House-Surgeon at the Dreadnought Hospital. Salary at the rate of £110 per annum, and a proportion of fees.

SHEFFIELD CITY.—Resident Medical Officer at the Winter Street Hospital for Tuberculosis (unmarried). Salary £350 per annum, rising to £450.

SOUTHAMPTON: ROYAL SOUTH HANTS AND SOUTHAMPTON HOSPITAL.—Junior House-Surgeon (male, unmarried). Salary at the rate of £150 per annum.

STOCKTON AND THORNABY HOSPITAL, Stockton-on-Tees.—(1) Senior Resident Medical Officer (Surgeon). (2) Second Resident Medical Officer (Physician). (3) Junior Resident Medical Officer. Salary £175, £150, and £125 per annum respectively.

SURREY COUNTY COUNCIL.—Assistant Medical Officer of Health (male). Salary £600 per annum, rising to £700.

SYDNEY UNIVERSITY.—Director of Cancer Research. Salary £2,000 per annum.

WAKEFIELD: CLAYTON HOSPITAL.—House-Surgeon (male). Salary at the rate of £150 per annum for first six months, rising to £175.

WEST LONDON HOSPITAL, Hammersmith Road, W.6.—(1) Honorary Medical Registrar; honorarium £100. (2) House-Physician. (3) Two House-Surgeons. Salary at the rate of £100 per annum for (2) and (3).

WINCHESTER: ROYAL HAMPSHIRE COUNTY HOSPITAL.—Honorary Surgeon in Ordinary.

WOLVERHAMPTON COUNTY BOROUGH.—Assistant Medical Officer for Maternity and Child Welfare Work. Salary £600 per annum.

WORCESTER GENERAL INFIRMARY.—Junior Resident Medical Officer. Salary £120 per annum.

CERTIFYING FACTORY SURGEONS.—Th[illegible] announced: Aylsham (Norfolk), [illegible] its are bridgeshire). Applications to the [illegible] (Cam-Office, Whitehall, S.W.1. [illegible], Home

This list of vacancies is compiled from our advertisement columns, where full particulars will be found. To ensure notice in this column advertisements must be received not later than the first post on Tuesday morning.

APPOINTMENTS.

DENNING, George F., M.R.C.S., L.R.C.P., Deputy Medical Officer, County Mental Hospital, Rainhill.

FURNISS, Ada, F.R.C.S.Edin., D.P.H.Manch., Assistant Medical Officer, Withington Hospitals and Institution, Nell Lane, West Didsbury, Manchester.

GOLDSMITH, William Noel, M.A., B.Chir.Camb., M.R.C.P.Lond., Physician for Skin Cases to the West End Hospital for Nervous Diseases, London.

HESLOP, A. H., D.S.O., O.B.E., M.B., B.S.Durh., F.R.C.S.Eng., Honorary Local Consulting Surgeon, King Edward VII's Convalescent Home for Officers, Osborne, Isle of Wight.

HOWELL, B. Whitchurch, F.R.C.S., Orthopaedic Surgeon to the Essex County Council.

SILVERSTON, Joseph D., M.B., B.S.Durh., Deputy Medical Officer, County Mental Hospital, Lancaster.

BIRTHS, MARRIAGES, AND DEATHS.

The charge for inserting announcement of Births, Marriages, and Deaths is 9s., which sum should be forwarded with the notice not later than the first post on Tuesday morning, in order to ensure insertion in the current issue.

BIRTHS.

CHESTER.—On March 2nd, at 27, Welbeck Street, W.1, to Aileen M. Chester, M.B., Ch.B., wife of Edgar S. Sibun, a son.

GALLOWAY.—On February 24th, to Margaret, the wife of Robert Menzies Galloway, M.D., D.P.H., of 237, Wigan Road, Bolton, a daughter.

SCHOFIELD.—At Fort Portal, Uganda, on January 24th, 1927, to Georgiana (*née* Armitage), the wife of A. T. Schofield, M.A., M.R.C.S., etc., of the Church Missionary Society, Toro Hospital, Fort Portal, Uganda, a daughter.

MARRIAGES.

[illegible] On February 17th, at the Register Office of St. Giles, [illegible]el McDonald, M.B., Ch.B.Vict., M.R.C.S.Eng., to Gladys May Bright, B.A., A.R.C.M.

MAGAN—STANTON.—On February 19th, at University Church, St. Stephen's Green, Dublin, by the Rev. T. A. Finlay, S.J., assisted by the Very Rev. Canon Donohoe, P.P., V.G., Francis J. Magan, Solicitor, Granard, co. Longford, to Sybil Stanton, M.B., B.Ch., B.A.O., daughter of Mrs. Stanton and the late John Stanton, Alexandra Place, Cork.

DEATHS.

FLETCHER PORTER.—On February 17th, after a long and painful illness, John Fletcher Porter, C.B.E., J.P., M.B.Lond., at 206, Upper Clapton Road, London, E.5.

HILLIER.—On February 22nd, at 396, Ecclesall Road, Sheffield, Robert John Hillier, M.R.C.S., L.R.C.P., aged 68.

PHILLIPS.—On February 18th, 1927, at Hardwick Lodge, Streetly, George Arthur Phillips, M.R.C.S., J.P., in his 78th year.

VAUGHAN GRIFFITH.—On February 23rd, 1927, at Bryn Darland, Coedpoeth, near Wrexham, North Wales, William Vaughan Griffith, L.R.C.S.E., L.R.C.P.E., L.F.P.S.G., aged 65 years.

Printed and published by the British Medical Association, at their Office, Tavistock Square, in the Parish of St. Pancras, in the County of London.

A TREATMENT FOR INSURED PERSONS.

Conference Summoned by the British Medical Association.

CONFERENCE on spa treatment for insured persons, summoned by the British Medical Association, was held in the Council Chamber of the Association's House in Tavistock Square on March 4th. Dr. H. Guy Dain (Chairman of the Insurance Acts Committee) presided, and representatives attended from the British Spa Federation, the British Committee on Rheumatism (which is a committee of the International Society of Medical Hydrology), the Spa Practitioners' Association, the Mineral Water Hospitals, the Federation of Medical and Allied Services, and the British Medical Association. The representatives of the last named, in addition to Dr. Dain, were Dr. E. R. Hethergill, Dr. C. O. Hawthorne, Mr. E. Lewis Lilley, and Dr. F. G. Thomson (Past-President). There were also present five representatives of approved societies—namely, Mr. W. A. Appleton (General Federation of Trade Unions), Mr. C. G. Izard (Prudential Approved Societies), Mr. G. L. Ingstrom (National Conference of Friendly Societies), and Mr. J. A. Newrick and Mr. S. Sanderson (National Association of Trade Union Approved Societies). The point of view of each organization or group of organizations was first stated in brief speeches.

Mr. John Hatton (British Spa Federation) stated that the beginning of any active movement to make spa treatment available for insured persons dated from the publication of the report of the Ministry of Health in 1924 on "The incidence of rheumatic diseases."[1] This report brought to a head a feeling of concern among many of the approved societies as to the number of their members drawing medical benefit on account of rheumatism without, apparently, anything very definite in the way of treatment. In July, 1924, a deputation of members of the United Patriots Friendly Society was received by the then Minister of Health (Mr. Wheatley), who undertook to notify the Royal Commission on National Health Insurance that the society desired to be heard on this subject. The society thereupon conferred with the British Spa Federation, and a scheme was drafted and presented to the Royal Commission, whose report, however, was curiously vague on all points of this kind, though it did suggest the possibility of including physiotherapy as an additional benefit. His federation understood that what the Ministry of Health would require before it could move officially would be a request from the approved societies that spa treatment should be made available as an additional benefit, and a general approval had already been given by various approved societies and groups. Mr. Hatton then gave an outline of the scheme suggested by the British Spa Federation. The scheme would be applicable to all insured persons suffering from "rheumatic diseases," according to the Ministry's classification of those conditions. A patient would be recommended for spa treatment by his insurance practitioner, and a report on his case prepared by the practitioner would be sent for the consideration of a medical board to be set up at the spa, which would decide whether the case was suitable. As far as possible patients would be sent to the spa nearest their own homes. To secure the full success of the scheme the best medical advice must be available for these persons at the spa. The help of the mineral water hospitals also was essential to the success of the scheme. The facilities they offered for x-ray examination and laboratory service would, of course, be paid for on a fair basis, and their physicians might form the spa medical board just mentioned, or the nucleus of it. These hospitals, which often had long waiting lists, could not deal with great numbers of insured persons as in-patients, but the majority of these cases would not require beds. Those that did so might be taken in at a certain charge so far as the accommodation of the hospital would admit, and if there was still room in hospital a certain number of cases which required special observation might be taken. Otherwise the patients on arrival at the spa would go to a consultation centre, and during their stay would attend there as often as required by the doctor in charge. They would be assigned for treatment at the bathing establishment. A capitation fee to cover all treatment and administration costs would be more satisfactory than any system of charging for individual treatments. He drew attention to the possibilities for research offered by this large amount of fresh clinical material coming to the spas, and the addition to the present spa hospitals of what was practically an elastic out-patient department. At each spa there should be set up a local committee of control, with representatives of the corporation or spa authority, the medical board, the spa hospitals, the approved societies, and the local insurance committee. A supervisory committee of members appointed by the local approved societies would attend to accommodation and impose discipline, but all medical matters would be dealt with by the medical board. He pointed out the difficulties attending the establishment of hostels at the spas, chiefly the great capital expense to the approved societies, and urged that at every spa there were cheaper boarding-houses where patients could be lodged and dieted under the directions laid down. The estimated cost of treatment and administration at the spa was 18s. a week, and of board and lodging 35s.

Mr. W. A. Appleton (General Federation of Trade Unions) said that the discussion from the approved societies' point of view was a little premature. Nothing could be done before the next valuation in 1928, and at that valuation it was by no means certain that there would be any surplus available. But the approved societies were interested, having observed that well-to-do people who frequented spas were generally benefited. They also desired some more systematic treatment of rheumatic disorder, not confined to spa treatment. They were prepared to make this an additional benefit if it could be done effectively and economically, but they could not commit themselves to large capital expenditures.

Sir Thomas Horder, Bt. (Federation of Medical and Allied Services), said that there was a broader aspect of the question than spa treatment. Sir George Newman had outlined—not so much for the Ministry's consideration as for the consideration of the medical profession, employers of labour, and representatives of approved societies—a comprehensive scheme, the first element in which would be the setting up of a clearing-house in large centres, where patients suffering from rheumatism could be examined and classified into early cases, able to work while under treatment, cases still curable but more tedious, and cases only partially curable. Cases belonging to the first of these classes would be treated at a clinic attached to the clearing-house, and in the main by physical methods; cases belonging to the second class would mostly be referred for spa treatment; and those in the third class would, as far as means were available, be treated in special hospitals. The second part of the scheme related to the establishment of an arthritic unit, and the third to an extension of the work at the spas, which would be brought into closer touch with the treatment of rheumatic persons in general. Sir Thomas Horder thought that the first thing to be done was to set up a combination of clearing-house and treatment centre in a situation easy of access for workers suffering from rheumatism. He was inclined to put

[1] British Medical Journal, March 1st, 1924, p. 395.

the expansion of work at the spas in the second place, rather than in the third, where Sir George Newman put it, and to reserve until last the establishment of an arthritic unit, which would be the most difficult part of the administration, for the reason that it could hardly be conceived of without beds, whereas the clearing-house and treatment centre, and to a large extent the spa work, would be of an out-patient character.

Dr. KERR PRINGLE (Spa Practitioners' Association) gave a definition of spa treatment—"treatment at a place possessing a supply of natural mineral waters of known therapeutic value, and facilities for their application." This, he said, implied the existence of suitable buildings, apparatus, and trained personnel for work in bath-houses and for physiotherapeutic departments. The treatment was a régime in which diet and exercise played an important part, and, while most forms of physiotherapy were employed, water-drinking and bathing were the principal therapeutic agents. The best economic results of spa treatment were obtained by the co-ordinated work of several departments in medicine. He was anxious for the reputation of the spas, which was not improved by the war, when the wrong persons were sent, and no control was exercised over them. The medical administration of the scheme should be carried out by the provision of out-patient departments at the special hospitals already existing in different spas, and the patients should be in hostels, because in boarding-houses it was difficult to arrange dietaries and to ensure compliance with regulations. The idea of his association was that there should be enlarged out-patient departments in connexion with the spa hospitals, the patients being seen on a certificate signed by an insurance practitioner. The medical staffs, of course, would have to be enlarged, and rosters formed.

Mr. C. A. RHODES, representing the mineral water hospitals of Bath, Harrogate, and Buxton, said that the hospitals were prepared to treat insured patients, at such a charge as would be adequate to meet expenses, and so far as the demands on their beds allowed. Most of the insured patients, however, would be out-patients, and those for whom he spoke held the view that they should be housed in hostels, established and maintained by the approved societies. No adequate treatment could be given unless the patients were [illegible] and under supervision. Speaking for his ow[illegible] he said that the first claim on its beds [illegible] patients sent by subscribers. The actual cost of maintenance and treatment was four guineas for a fortnight, but, of course, in the case of insured patients, who were not charity patients, and did not wish to be, the medical men would expect payment, and there would be other charges.

Dr. R. FORTESCUE FOX (British Committee on Rheumatism) said that his committee was favourably situated for preparing some preliminary policy on this matter, as through its parent body, the International Society of Medical Hydrology, it was in touch with medical men in most of the European countries where rheumatism was being systematically treated by Government organizations. The treatment centre or clinic was the primary part of the scheme, and research also was very important. In Germany it was recognized that the spas held such an important place in the national treatment of rheumatism that one spa had been deliberately selected as a centre for research in this subject. The provision of a research centre in this country at one or more spas should certainly be considered.

Dr. DAIN said that the British Medical Association was interested in this question on two sides—namely, on the scientific side, and in connexion with the organization of medical services. This was a proposal to extend a medical service to a particular class of the community, and the Association was interested to ensure that the organization should fit in with other services and have useful results. As an insurance practitioner, if he were asked what he wanted most, he would say that he wanted facilities for discovering the cause of the rheumatism in the individual case. Until that had been elicited, he had no special use for spa treatment, for he had no means of knowing whether he was sending a patient to a spa at a time and in a condition when he would get the full value of the treatment provided. He fully appreciated the regard which speakers on behalf of the spas had had for the reputation of the spas. It was not advantageous from the point of view of the spas' reputation, nor was it economically sound, to send patients to spas before their cases had been properly investigated, and before it was discovered whether spa treatment was really wanted. Associated with any organization for the treatment of rheumatism there must be some machinery by which the insurance practitioner might obtain facilities for completing his diagnosis. It was obvious from the history of the spas that a great many patients did receive very important benefit.

In the course of some general discussion, Mr. J. A. NEWRICK (National Association of Trade Union Approved Societies) said that he was satisfied that in his own industry (iron and steel) a great deal of rheumatism could be prevented simply by the dissemination of information. Mr. G. L. LINGSTROM, another approved societies' representative, said that the committee of the National Conference of Friendly Societies was about to approach the Ministry on the question of cost.

Dr. F. G. THOMSON (British Medical Association) was doubtful as to the practicability of setting up diagnostic and treatment units in the various centres to deal with chronic rheumatism. The out-patient departments of hospitals could surely be trusted to select the cases with a view to particular forms of treatment, and as for research, ordinary clinical research could be carried out at all local hospitals, while special advanced research into the different types of rheumatic disorder was being carried out at the present time at the different spas. Dr. J. B. BURT (Spa Practitioners' Association) said that the spas made no claim of competence to deal with the whole question of rheumatism, but they could do a great deal, and he thought that without any large provision of capital they could accommodate themselves to treat 20 or 30 per cent. more cases than they did at present. Mr. HATTON, dealing with the question of hostels, said that while such provision was ideal, it involved capital expenditure which made it not a practicable proposition at the moment, and he also quoted German experience to show that patients objected to being labelled in this way, and that on that ground, as well as on the ground of expense, some German authorities had found it necessary to use existing hotel accommodation.

Appointment of Drafting Committee.

Dr. D. A. COLES (Federation of Medical and Allied Services) urged the immediate necessity of getting to work, and accordingly moved:

> That a centre be initiated at once for research, education, and treatment relating to rheumatism, and that this centre be located, to begin with, in London, working in collaboration with all provincial centres, whether spa or otherwise.

Dr. M. B. RAY seconded this resolution.

Dr. J. B. BURT (Spa Practitioners' Association) also brought forward a resolution, which it was agreed should be taken first:

> That a small committee be elected, with a representative from each body taking part in this Conference, who, together with the Chairman of the Conference, are requested to draft and submit to a further meeting (in May or June) a scheme under which steps should be taken to provide as soon as possible increased facilities for diagnosis and treatment of the insured rheumatic population.

This was seconded by Mr. HATTON, and supported by Dr. E. R. FOTHERGILL (British Medical Association), who said that what general practitioners wanted was to have at their disposal more efficient means of diagnosis and consultation. Dr. G. E. SAWDON and Dr. G. HOLMES (Spa Practitioners' Association) also spoke to the resolution. Mr. LEWIS LILLEY (British Medical Association) thought that the arrangements might have two parts—a consultation centre which would take the responsibility of ordering spa treatment, and the management of that treatment which would be carried out under contract with the authorities of the spa.

Sir WILLIAM WILLCOX (British Committee on Rheumatism) said that chronic rheumatism was not a disease; it was a manifestation of some chronic toxaemia. One-sixth of the existing invalidity was due to rheumatism. He thought it would be disastrous if this matter were pigeon-holed in spas, or indeed in any section of medical practice. The need was to organize and combine existing facilities. At the same time, the spas did offer one admirable means of treating rheumatism, and he would on no account belittle it. There was also a need in London and large towns for clinics where physical methods could be provided. Very few of the hospitals in London had departments which were adequate to deal with chronic rheumatism cases. It was also well to remember that chronic rheumatism was, almost more than any other disease, preventable, and its investigation would result in great gain from the point of view of prevention as well as that of treatment of existing sufferers.

Mr. APPLETON said that if the approved societies' representatives did not vote on the resolution before the Conference it was not because they were unsympathetic, but because they could not commit their constituents. If this committee were agreed to they would certainly place the matter before their respective bodies, and do their best to secure the co-operation of the approved societies in the work of the committee.

The CHAIRMAN said that in that case the procedure would be for the committee not to start its work until an intimation was received that the approved societies were prepared to come in.

Some discussion then took place on the constitution of the proposed committee. Mr. NEWRICK thought it hardly fair to have seven or eight representatives of what might be called the "producers" side, and only one representative of the "consumers." The CHAIRMAN said that that was reasonable, and he suggested, the mover of the resolution concurring, that the number of approved societies' representatives on the committee should be left over until the societies themselves were able to make a proposition. He resisted, however, a request that

the British Spa Federation should have more than one member, pointing out that, after all, this was only to be a small committee to draft a scheme which would be submitted to another conference.

On this understanding Dr. Burt's resolution was carried without dissent, the approved societies' representatives not voting, for the reason stated by Mr. Appleton, and the resolution moved by Dr. Coles was, with his consent, held over to be referred to the committee when in being.

On the motion of Alderman COOPER (British Spa Federation) a hearty vote of thanks was accorded to the British Medical Association for calling the Conference, and to Dr. Dain for presiding.

Association Notices.

BRANCH AND DIVISION MEETINGS TO BE HELD.

BIRMINGHAM BRANCH.—The fifth ordinary meeting of the Birmingham Branch will be held at the Medical Institute, Birmingham, on March 17th, at 3.30 p.m., when the President, Dr. H. G. Dain, will take the chair. Mr. Naughton Dunn will read a paper upon "Modern principles in the treatment of common disabilities of bones and joints."

LANCASHIRE AND CHESHIRE BRANCH: HYDE DIVISION.—At the meeting of the Hyde Division to be held in the Dukinfield Town Hall on Thursday, March 17th, at 8.30 p.m., Dr. Robertson will deliver his presidential address.

METROPOLITAN COUNTIES BRANCH: CITY DIVISION.—The clinical meeting arranged for to-day (Friday, March 11th) has been postponed to Friday, March 18th. The Divisional fancy dress dance will be held in the Great Hall of the British Medical Association House, Tavistock Square, W., on Thursday, March 24th, at 8.30 p.m. to 1.30 a.m. Le Saire's Band. Refreshments by Gunters, Ltd. Fancy dress optional; four prizes. A demonstration by professional dancers will be given during the evening. Tickets (8s. inclusive) can be obtained from Dr. G. Clark Trotter, 2, Tyndale Place, Islington; Dr. Harold Latham, 2, Hemingford Road, Barnsbury, and from the secretary, Dr. Worley, 45, De Beauvoir Road, N. Early application is requested.

METROPOLITAN COUNTIES BRANCH: LEWISHAM DIVISION.—A clinical evening will be held by the Lewisham Division at the South Eastern Children's Hospital, Sydenham, on Tuesday, March 15th.

METROPOLITAN COUNTIES BRANCH: NORTH MIDDLESEX DIVISION.—At the meeting of the North Middlesex Division on March 30th Dr. G. W. H. French will read a paper on "Differential diagnosis of the acute abdomen."

METROPOLITAN COUNTIES BRANCH: SOUTH-WEST ESSEX DIVISION.—A meeting of the South-West Essex Division will be held at the Walthamstow Hospital on Tuesday, March 29th, at 3.30 p.m. Dr. G. F. Still will give an address on "*Vomiting in childhood.*"

METROPOLITAN COUNTIES BRANCH: WILLESDEN DIVISION.—A meeting of the Willesden Division will be held at the Willesden General Hospital, Harlesden Road, on Wednesday, March 16th, at 9 p.m. Agenda: Correspondence, etc.; Dr. A. Hope Gosse (St. Mary's Hospital) will give an address on "Clinical disorders of the heart"; election of representative and deputy representative for Annual Representative Meeting at Edinburgh.

MIDLAND BRANCH: CHESTERFIELD DIVISION.—A meeting of the Chesterfield Division will be held at the Maternity Hospital, Chesterfield, on Friday, March 25th, at 8.15 p.m. Mr. A. M. Webber, F.R.C.S., surgeon to the Nottingham Hospital, will give an address on "Observations on hysterectomies." Tea and coffee served at 8 p.m.

NORFOLK BRANCH.—A meeting of the Norfolk Branch will be held at the Norfolk and Norwich Hospital on Wednesday, March 16th, at 3.30 p.m., when the President, Dr. W. M. Fisher, will take the chair. Dr. Sydney H. Long will give a demonstration, with cinematograph films, on "Manifestations of syphilis and gonorrhœa." Tea will be served at 4.45.

NORTH OF ENGLAND BRANCH.—A scientific meeting of the North of England Branch will be held at Greenbank Hospital, Darlington, on Thursday, March 17th. 2.30 p.m., Mr. A. Thacker *Neville*: Laryngology and ophthalmology in relation to general practice; 3 p.m., Mr. R. J. Willan: Some common but obscure cases of acute abdominal pain; 3.30 p.m., Dr. George Hall: Minor endocrine defects; 4 p.m., tea; 4.15 p.m., Mr. H. C. Pearson: Modern electro-therapeutics; 4.45 p.m., Mr. D. S. Falconer: Food disorders in infancy. The annual dinner of the Branch will be held at the Central Station Hotel, Newcastle-on-Tyne, on the same evening at 7 for 7.30 o'clock; the President of the Branch, Mr. W. S. Dickie, F.R.C.S., will take the chair. Tickets 10s. 6d. *Applications* for seats should be made to Mr. Norman Hodgson, honorary secretary, 7, Windsor Terrace, Newcastle-on-Tyne, before March 14th.

NORTH OF ENGLAND BRANCH: NEWCASTLE-ON-TYNE DIVISION.—A reception and dance will be held by the Newcastle-on-Tyne Division at the College of Medicine, Newcastle-on-Tyne, on Thursday, March 31st, at 8.30 p.m. to 1 a.m. Dr. and Mrs. A. Livingston will receive the guests. During the evening a cabaret show will be given by the College of Medicine Concert Party, and [illegible] will be made for those desiring [illegible] will be available. Cars may be [illegible] east of the College of Medicine [illegible] each. Members are asked to m[illegible]

NORTH OF ENGLAND BRANCH: [illegible] meeting of the Sunderland Di[illegible] will be held at the Royal Infirmary Sunderland, on Wednesday, March 16th, at 8.15 p.m. Mr. F. C. Pybus, M.S., F.R.C.S., will give an address on deformities. All members of the Division are invited to be present.

SOUTH WALES AND MONMOUTHSHIRE BRANCH: NORTH GLAMORGAN AND BRECKNOCK DIVISION.—A meeting of the North Glamorgan and Brecknock Division will be held on Thursday, March 24th, when Dr. T. F. Cotton will deliver a British Medical Association Lecture on "*Prognosis and treatment of heart disease.*"

STAFFORDSHIRE BRANCH: SOUTH STAFFORDSHIRE DIVISION.—At the meeting of the South Staffordshire Division to be held on Tuesday, March 29th, Dr. T. Watts Eden, F.R.C.P., will give a British Medical Association Lecture on "Prevention and treatment of eclampsia."

SURREY BRANCH: CROYDON DIVISION.—A meeting of the Croydon Division will be held at the Croydon General Hospital on Tuesday, March 22nd, at 8.30 p.m. Professor Verney will read a paper on "Pharmacology and practice."

SUSSEX BRANCH: BRIGHTON DIVISION.—A clinical meeting of the Brighton Division will be held at the Children's Hospital on Wednesday, March 16th, at 3.45 p.m.

VACANCIES.

BELGRAVE HOSPITAL FOR CHILDREN, Clapham Road, S.W.9.—(1) House-Surgeon. (2) Assistant House-Physician. Males. Salary at the rate of £100 *per annum each.*

CAMBRIDGE: ADDENBROOKE'S HOSPITAL.—(1) House-Physician. (2) House-Surgeon. (Males, unmarried.) Salary at the rate of £130 per annum each.

CENTRAL LONDON OPHTHALMIC HOSPITAL, Judd Street, W.C.1.—Senior and Junior House-Surgeons. Salary £100 and £50 per annum respectively.

CHARING CROSS HOSPITAL, W.C.2.—Assistant Obstetric Physician.

CHESTER ROYAL INFIRMARY.—Honorary Assistant Anæsthetist.

COSSHAM MEMORIAL HOSPITAL, Kingswood, Bristol.—Resident Medical Officer (male). Salary £150 per annum.

DORSET COUNTY HOSPITAL, Dorchester.—Second Honorary Physician.

DUBLIN UNIVERSITY MISSION HOSPITAL, Chota Nagpur, India.—Female Doctor.

DURHAM COUNTY HOSPITAL.—Junior House-Surgeon (male). Salary £120 per annum.

EDMONTON UNION.—Medical Officer for the Waltham Abbey District of the Edmonton Union. Salary £135 per annum.

ELIZABETH GARRETT ANDERSON HOSPITAL, Euston Road, N.W.1.—Physician in charge of the Children's Department.

ESSEX COUNTY COUNCIL.—Assistant County Medical Officer of Health. Salary £700 per annum.

GLASGOW UNIVERSITY.—Muirhead Chair of Obstetrics and Gynæcology.

GORDON HOSPITAL FOR RECTAL DISEASES, Vauxhall Bridge Road, S.W.—Resident House-Surgeon. Salary £75 per annum.

HALIFAX: ROYAL HALIFAX INFIRMARY.—Third House-Surgeon (male). Salary at the rate of £100 per annum.

HARROGATE INFIRMARY.—House-Surgeon (male).

HEREFORDSHIRE COUNTY AND CITY MENTAL HOSPITAL.—Second Assistant Medical Officer (male, unmarried). Salary £350 per annum.

HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, Brompton, S.W.3.—Assistant Surgeon to the Throat, Nose and Ear Department.

HOSPITAL FOR EPILEPSY AND PARALYSIS, Maida Vale, W.9.—Honorary Medical Officer in charge of X Ray and Electro-therapeutics.

HOSPITAL FOR SICK CHILDREN, Great Ormond Street, W.C.1.—(1) House-Surgeon. (2) House-Physician and Assistant Casualty Officer. Salary £50 for six months each.

HOSPITAL OF ST. JOHN AND ST. ELIZABETH, 40, Grove End Road, N.W.8.—Assistant Physician.

IPSWICH: EAST SUFFOLK AND IPSWICH HOSPITAL.—(1) Two House-Surgeons. (2) House-Physician. Salary at the rate of £100 per annum each.

KETTERING AND DISTRICT GENERAL HOSPITAL.—Resident Medical Officer. Salary at the rate of £175 per annum.

This list of vacancies is compiled from our advertisement columns, where full particulars will be found. To ensure notice in this column advertisements must be received not later than the first post on Tuesday morning.

DIARY OF SOCIETIES AND LECTURES.

ROYAL SOCIETY OF MEDICINE.

War Section.—Mon., 5 p.m., Surgeon Commander C. H. Dawe: Diet and Disease in the Navy.

General Meeting of Fellows, Tues., 5.30 p.m.

Section of Pathology.—Tues., 8.30 p.m., Annual General Meeting. Professor H. T. Deelman: Injury and Repair in the Development of Cancer, and the Growing of Experimental Cancers; Dr. Oliver Heath: The Defence Process in the Body in Typhoid Fever; Professor McIntosh: Experiments on Immunity with the Rous Sarcoma.

Section of Comparative Medicine.—Wed., 6 p.m., Professor Moellgaard y, with Special Reference to Heavy Metals. e.—Wed., 5 p.m., Sir D'Arcy Power: The Surgeons as Literature; Professor Morpurgo at the University of Padua in the Collegio r. C. Singer: An Example of the Egyptian God Bes exhibiting Symptoms of Spina Bifida; Dr. Herbert Spencer: (1571), with Notes on Two MS. Copies. m., Cases and Demonstration. 5 p.m.,

Section of Obstetrics and Gynaecology.—Fri., 8 p.m., *Specimens.* Paper—Mr. Aleck Bourne and Dr. J. H. Burn: The Dosage and Action of Pituitary Extract and of the Ergot Alkaloids on the Uterus in Labour, with a Note on the Action of Adrenaline.

Section of Electro-Therapeutics.—Fri., 8.30 p.m., Discussion: Cholecystography. Opener: Dr. N. S. Finzi.

ROYAL COLLEGE OF PHYSICIANS OF LONDON, Pall Mall East, S.W.—Tues. and Thurs., 5 p.m., Goulstonian Lectures by Professor F. R. Fraser: Cardiac Dyspnoea.

ROYAL COLLEGE OF SURGEONS OF ENGLAND, Lincoln's Inn Fields, W.C.—Mon., 5 p.m., Sir Arthur Keith: The Peoples of the East—Past and Present. Wed., 5 p.m., Dr. H. Carlill: Simulation of Surgical Affections by Hysteria. Fri., 5 p.m., Mr. R. St. Leger Brockman: Toxaemia and Acute Intestinal Obstruction.

ROYAL SOCIETY OF TROPICAL MEDICINE AND HYGIENE.—A Laboratory Meeting at Royal Army Medical College, Thurs., 8.15 p.m. Demonstrations by Drs. S. Adler and A. Balfour, Major J. S. K. Boyd, Major C. R. Chadwick, Mr. C. MacHattie, Mr. C. A. Hoare, Drs. Saiki, E. C. Smith, H. H. Scott, A. C. Stevenson, C. M. Wenyon, Professor Warrington Yorke, and Dr. A. R. D. Adams.

BIOCHEMICAL SOCIETY, Department of Physiology and Biochemistry, University College, W.C.—Fri., 3 p.m., F. M. Haines: Propelling Air round Small Circuits; P. and M. G. Eggleton: Chemistry of Phosphagen; R. K. Cannan and B. C. Knight: Pyocyanine. 4.30 p.m., B. and E. Holmes: Carbohydrate Metabolism of Brains in Normal and Diabetic Animals; P. and M. G. Eggleton: Phosphagen; C. Rimington and H. D. R. K. Cannan and B. C. J. G. Knight: L. C. Baker and G. F. Marrian: Baker, G. F. Marrian, and J. C. Drummond: The Adrenals of Rats and Vitamin B; S. Kon and J. C. Drummond: Vitamin B Deficiency and Inanition; A. Hassan and J. C. Drummond: Dietary Factors in Yeast; H. J. Channon and A. C. Chibnall: Calcium Salts of Glyceridephosphoric Acids in Cabbage Leaf Cytoplasm; O. Rosenheim: Sterol Colour Reactions and Vitamin A; M. H. Roscoe: The Dual Nature of Vitamin B; R. V. Stanford: (1) Automatic Apparatus for Removal of Ammonia from Solutions; (2) A Device for Preventing "Bumping" in Boiling Liquids.

CHELSEA CLINICAL SOCIETY, Rembrandt Hotel, Thurloe Place, S.W.7.—Tues., 7.30 p.m., Dinner. 8.30 p.m., Discussion: Professional Regrets; to be opened by Dr. Russell Andrews.

MEDICAL SOCIETY OF LONDON, 11, Chandos Street, W.1.—Mon., 8.30 p.m., Demonstration on Lipiodol Injections by Dr. Jacques Forestier.

POST-GRADUATE COURSES AND LECTURES.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION, 1, Wimpole Street, W.1.—Special Lecture at the Medical Society, 11, Chandos Street, W.1, Thurs., 5 p.m.: Common Mistakes in the Diagnosis and Treatment of Acute Abscess.* *Samaritan Hospital,* Marylebone Road, N.W.: Demonstration in Gynaecology, Fri., at 2 p.m., by Mr. Bourne.* *Central London Ophthalmic Hospital,* Judd Street, W.C.: Wed., at 4 p.m., Demonstration in Ophthalmology by Mr. Davenport.* (* Open to members of the medical profession, without fee.) *Chelsea Hospital for Women,* Arthur Street, S.W.: Special Course in Gynaecology, mornings and/or afternoons. Fee £5 5s. for two weeks' course.

CENTRAL LONDON THROAT, NOSE AND EAR HOSPITAL, Gray's Inn Road, W.C.1.—Fri., 4 p.m., Acute Mastoiditis: its Diagnosis and Treatment.

HOSPITAL FOR SICK CHILDREN, Great Ormond Street, *W.C.1.—Thurs., 4 p.m.,* Acute

LONDON lin's Hospital, Leicester Square, W.C.2. p.m., Pathology Demonstration.

NATIONAL —Mon., Tues., Thurs., and Fri., 2 p.m. noon, Pathology of the Nervous System; 3.30 p.m., Progressive Muscular Wasting. Tues., 3.30 p.m., Tumours of the Spinal Cord. Thurs., 3.30 p.m., Paraplegia. Fri., 12 noon, Anatomy and Physiology of the Nervous System; 3.30 p.m., Pituitary Tumours. Operations: Tues. and Fri., 9 a.m.

NORTH-EAST LONDON POST-GRADUATE COLLEGE, Prince of Wales's General Hospital, Tottenham, N.15.—Mon., 10 a.m., Surgical Clinic; 2.30 to 5 p.m., Medical, Surgical, and Gynaecological Clinics; Operations. Tues., 2.30 to 5 p.m., Medical, Surgical, Throat, Nose, and Ear Clinics; Operations. Wed., 2.30 p.m., Demonstration of Dermatological Cases; 2.30 to 5 p.m., Medical Skin and Eye Clinics; Operations. Thurs., 11.30 a.m., Dental Clinics; 2.30 to 5 p.m., Medical, Surgical, and Ear, Nose, and Throat Clinics; Operations. Fri., 10.30 a.m., Throat, Nose, and Ear Clinics; 2.30 p.m., Demonstration of Surgical Cases; 2.30 to 5 p.m., Surgical, Medical, and Children's Diseases Clinics; Operations: 4.30 p.m., Demonstration on Selected Cases of Nerve Diseases.

ROYAL NORTHERN HOSPITAL, Holloway Road, N.—Tues., 3.15 p.m., *Demonstration of Pathological Specimens.*

WEST LONDON HOSPITAL POST-GRADUATE COLLEGE, Hammersmith, W.6.—Mon., 10 a.m. to 1 p.m., Genito-urinary Operations, Skin Department, Surgical Wards; 2 p.m., Surgical Wards, Tues., 10 a.m. to 1 p.m., Lecture o Venereal Diseases and Chest Ca Nose, and Ear Department. Wed. Out-patients, Medical Wards, D 2 p.m., Surgical Wards, Eye Department. Thurs., 10 a.m. to 1 p.m., Neurological Department, Demonstration of Fractures; 2 p.m., Eye and Genito-urinary Departments, Gynaecological Wards. Fri., 10 a.m. to 1 p.m., Gynaecological Operations, Dental, Skin, and Electrical Departments; 2 p.m., Throat, Nose, a -10 a.m. to 1 p.m., Bacterial Therapy Depart Department. Daily: Operations, Medical and S p.m.

GLASGOW POST-GRADUATE MEDICAL Infirmary: Wed., 4.15 p.m., Medical Cases.

JAMES MACKENZIE INSTITUTE FOR CLINICAL RESEARCH, St. Andrews.—Tues., 4 p.m., Herpes.

British Medical Association.

CURRENT NOTES.

Edinburgh Annual Meeting: Reduced Railway Fares.

We are glad to be able to announce, on the authority of the Railway Clearing House, that the usual concession to members of the British Medical Association in regard to railway fares will apply to the Annual Meeting in Edinburgh this summer. The railway companies in Great Britain (except the Metropolitan, Metropolitan District, and London Electric Railway Companies) have agreed to issue passenger tickets to Edinburgh, available from July 13th to 25th, at the ordinary single fare and one-third for the double journey, fractions of 3d. being reckoned as 3d., with a minimum adult fare of 1s. A printed voucher of the usual kind, duly filled in by the applicant and signed by the Financial Secretary of the Association, must be given up at the booking office when the ticket is bought. These vouchers will be obtainable in due course on application to the Finance Department, British Medical Association, Tavistock Square.

Some Recent Work at Headquarters.

On March 1st the Pathological Committee of the British Medical Association considered and discussed with representatives of the newly formed British Pathologists Association certain suggestions the latter body had made in connexion with the report which was before the Council of the British Medical Association on December 15th last. As the result of the discussion certain modifications were made in the original recommendations, and an amended report will be presented to the next meeting of Council.

Propaganda Subcommittee.

Among other items of interest the Progaganda Subcommittee on March 2nd had under consideration the programme for the Secretaries' Conference at Edinburgh next July and the forthcoming issue of the Association's *Handbook*. A report upon the attitude of the lay press towards the profession and the Association since the last meeting showed the unusually wide publicity accorded to the work of the Association in connexion with tests for drunkenness. The report on this subject (published in the SUPPLEMENT of February 19th, p. 53) has received even more general notice than did the Hastings Lecture.

Disciplinary Machinery.

The Disciplinary Subcommittee of the Insurance Acts Committee met on March 3rd, and reviewed the whole field of disciplinary procedure in connexion with the National Health Insurance Acts. Proposals for improvement were formulated for submission to the Insurance Acts Committee, and will come before it at its next meeting.

Defence of Research.

On March 4th the Science Committee had under consideration the Council's instruction to organize medical opposition to any active parliamentary or extra-parliamentary agitation in favour of the Dogs' Protection Bill. The attempts of the Canine Defence League to secure prohibition of the use of dogs for experimental purposes have been dealt with in detail in a leading article in the JOURNAL of February 26th last. The position clearly calls for prompt and firm action in defence of legitimate research. In pursuance of the programme laid down by the Science Committee, a deputation under the leadership of Dr. Hawthorne, its chairman, met the medical members of Parliament at the House of Commons on March 9th. The medical M.P.s were unanimous in their expression of sympathy with the representations of the deputation. The Association is taking the opportunity afforded by the Lister centenary celebrations in London early next month to convene a conference of the chief medical and scientific societies directly interested in the question. It is hoped to secure a fully representative gathering, and invitations will be issued to the press. Meanwhile the Divisions of the Association have been requested to approach local members of Parliament, explaining to them the attitude of the profession in relation to the Dogs' Protection Bill, and urging them to vote against the bill on second reading. A petition against the bill has been circulated among the medical members of university staffs, medical schools, and teaching hospitals.

Hospital Policy.

Mention has been made in recent Current Notes of the increasing interest shown by the medical profession in the problems of hospital policy, and also the increasing difficulties in the way of general adoption of contributory schemes. The Hospitals Committee on March 9th had under review a memorandum for circulation amongst the medical staffs of hospitals dealing in detail with the application of the Association's policy to such schemes.

The memorandum was approved, and will be issued shortly. The committee is taking counsel's opinion on the possibility of recovering some payment in respect of accident cases received and treated by voluntary hospitals when the victim is either in a position to pay for treatment or to recover damages from some other party in connexion with the accident. Attention was drawn by Sir John Paget, K.C., at a recent meeting of the British Hospitals Association, to the difficulties arising in this connexion.

Medical Certificates for Injured Workmen.

On March 10th Dr. Bone, Dr. William Paterson, the Medical Secretary, and Dr. Courtenay Lord (Assistant Medical Secretary) had an interview with representatives of the Accident Offices Association with a view to ascertaining the exact position of the accident offices in the matter of medical certificates required in respect of men injured at their work. They obtained some very clear information on this subject, which will be reported to the Medico-Political Committee.

Poisons and Pharmacy Acts.

On March 4th Dr. J. W. Bone, Mr. Lewis Lilley, F.R.C.S., and the Medical Secretary gave evidence before the Departmental Committee which is inquiring generally into the existing machinery regulating the sale, keeping, distribution, and supply of poisons. The deputation emphasized the urgent need for consolidation of the present Poisons and Pharmacy Acts, and appealed to the committee to refrain from recommending the adoption of any additional regulations or restrictions calculated to hamper the work of either doctor or pharmacist.

Medical Secretary's Visits.

On March 8th Dr. Cox was present at the first dinner of the Doncaster Division (reported at page 93), and next evening had the pleasure of attending the Chesterfield Division dinner, when a presentation was made to Dr. Pooler, for many years honorary secretary of that very active Division. At Cardiff on Saturday, March 12th, Dr. Cox attended a meeting of colliery and works surgeons called by the South Wales Contract Practice Subcommittee, at which the position of the profession in regard to the long coal stoppage was discussed, and the honorary secretaries of the committee were instructed how to advise the doctors affected.

Sir Charles Hastings Clinical Prize Competition, 1928.

"The Sir Charles Hastings Clinical Prize" of fifty guineas, the second award for which will shortly be made by the Council of the British Medical Association, is again open for competition. The Prize has been established by the Association for the purpose of stimulating systematic observation, research and record in general practice. The Association believes that systematic observation by general practitioners, along selected lines of clinical study, may result in the production of practical contributions of great value by those who are in a favourable position for following disease through its various stages. The following are the conditions governing the award of the next Prize:

Regulations.

1. This prize is established by the Council of the British Medical Association for the promotion of systematic observation, research and record in general practice; it includes a money award of the value of fifty guineas.

2. Any member of the Association who is engaged in general practice is eligible to compete for the prize.

3. The work submitted must include personal observations and experience collected by the candidate in general practice, and a high order of excellence will be expected. If no essay entered is of sufficient merit no award will be made.

4. Essays, or whatever form the candidate desires his work to take, must be sent to the Medical Secretary, British Medical Association House, Tavistock Square, London, W.C.1, not later than December 31st, and the prize will be awarded at the Annual General Meeting of the Association.

5. No study or essay that has been published in the medical press or elsewhere will be considered eligible for the prize, and a contribution offered in one year cannot be accepted in any subsequent year unless it includes evidence of further work.

6. If any question arises in reference to the eligibility of the candidate or the admissibility of his essay, the decision of the Council on any such point shall be final.

7. Each essay must be typewritten or printed, must be distinguished by a motto, and must be accompanied by a sealed envelope marked with the same motto, and enclosing the candidate's name and address.

8. The writer of the essay to whom the prize is awarded may, on the initiative of the Science Committee, be requested to prepare a paper on the subject of his essay for publication in the *British Medical Journal* or for presentation to the appropriate Section of the Annual Meeting of the Association.

9. Inquiries relative to the prize should be sent to the Medical Secretary, address as above.

Association Prizes for Essays by Medical Students.

The Council of the Association gave notice in July last that it was prepared to award prizes of £10 each for essays by final-year students on "Three types of cases of thyroid enlargement, with their treatment." The essays have been examined by the following members of the Association: Mr. T. P. Dunhill, C.M.G., M.D., B.S. (London), Professor T. R. Elliott, C.B.E., D.S.O., F.R.C.P., F.R.S. (London), Professor G. R. Murray, M.D., F.R.C.P. (Manchester), Mr. G. Grey Turner, M.S., F.R.C.S. (Newcastle-on-Tyne). In accordance with the examiners' marks, prizes—a certificate signed by the President of the Association and a cheque for £10 in each case—have been awarded as follows:

Group of Medical Schools.	*Prize-winner.*
University of Birmingham; University of Bristol; University of Wales.	Mr. E. R. L. DAVIES, Welsh National School of Medicine.
University of Durham; University of Leeds; University of Sheffield.	Mr. MAX ABRAMS, Leeds University.
University of Edinburgh; School of Medicine of the Royal Colleges.	Miss GEORGINA M. H. SOMERVILLE, Edinburgh University.
University of Glasgow; Anderson College of Medicine; Queen Margaret College School of Medicine for Women; St. Mungo's College.	Mr. M. A. MACKEY, Glasgow University.
Charing Cross Hospital Medical School; King's College Hospital Medical School.	Miss FLORENCE M. PARSONS, *Charing* Cross Hospital Medical School.
Guy's Hospital Medical School; London Hospital Medical School.	Mr. E. R. HOLIDAY, London Hospital Medical School.
London (Royal Free Hospital) School of Medicine for Women; University College Hospital Medical School.	Miss HELEN NEWMAN, London School of Medicine for Women.
St. Bartholomew's Hospital Medical School; St. George's Hospital Medical School.	Mr. H. J. BURROWS, St. Bartholomew's Hospital.
St. Thomas's Hospital Medical School; Westminster Hospital Medical School.	Mr. P. A. M. SOUTTER, Westminster Hospital.
Medical Schools in British Empire outside the British Isles.	Mr. C. D. COSTELLO, Otago Medical School, New Zealand.

The prizes in respect of the London groups were presented to the winners at the meeting for senior students and recently qualified medical practitioners held in the Great Hall of the Association on February 24th. The prizes in respect of the other groups will, as far as possible, be presented at meetings held by the Divisions or Branches concerned to welcome the newly qualified members of the profession in their respective areas. Full particulars of the result of the competition have been sent by post to the deans of the medical schools and to all the competitors.

Annual Meeting of American Medical Association.

As was stated in our issue of February 19th, the seventy-eighth annual session of the American Medical Association will be held in Washington from May 16th to 20th inclusive, and the Council of the British Medical Association has been invited to appoint official delegates. The Medical Secretary will be glad to know of any member of the Association who is likely to be visiting the United States at that time.

THE report in last week's SUPPLEMENT of the Conference on Spa Treatment for Insured Persons, held at the Association's House on March 4th, should have included the name of Dr. Arthur Manknell of Bradford as one of the representatives of the British Medical Association.

Association Notices.

FORMATION OF ASHFORD, DOVER, AND FOLKESTONE DIVISIONS.

NOTICE is hereby given to all concerned of the formation of Ashford, Dover, and Folkestone Divisions of the Kent Branch, in substitution for the Dover and Folkestone Division of that Branch, with areas as follows:
